I think some of the references in this thread are older than necessary. The first electronic book that I ever bought was the first ham book I ever bought, "How to Become a Radio Amateur" in 1971. It had a single tube transmitter of the sort of design being searched for, complete with being build on a homemade wooden chassis. That sort of design would not have changed much over the years, up until the point where single transistor transmitters repleaced them. I sadly gave that book away a long time ago.

I just checked my Handbooks, though, and I'm surprised that the single tube transmitter is not there. Not in 1971 (it's two stages), not in 1968 (it's a two stage too) but the 1961 edition has a 6DQ6A tranmsitter. But the single tube transmitter was all over the place when I was first licensed, in magazines and in books, so it still must be fairly easy to find an article about it without going to a 1930's QST.

Try Popular Electronics, Electronics Illustrated and Radio-TV Experimenter
circa 1965-1975. I'm pretty sure that PE had at least two breadboard
40 meter one or two tube CW transmitter projects in that time range.

Ted shouldn't be asking questions on the rec.radio.AMATEUR.homebrew
newgroup, if he doesn't want responses from hams.

Besides that, I don't think running 5mW on 6M without a licence would
stop the world.

Hi,

SQR is a programming function and stands for Square. (Not square root ,
which is usually expressed SQRT).

ie. Pout = (Vce) x (Vce) / (2 x Rl) = 0.1 W

I am not getting 0.1 W out.

Do you have any other possibilities I could explore.

Regards
Dave Huisman

Yes indeed we used to put 2 volt 60 ma bulbs in series with the crystals
to at least determine just how much current was being drawn. In the
Tri-tet circuit, it was essential. If you mis-tuned the fool thing, you
were sure to loose a crystal---even the old, monster units! Cliff K7RR

Source record: 79841

Years ago, I used clear acetate from DATAK (or whoever) in a copy machine and then did the ironing and was not pleased with the results. Then I tried toner on the special paper sold by I-forget-the-name. It too was not satisfactory in my opinion. I did plenty of experimenting on ironing temperature and time.

Then about a year ago, I was asking similar questions on a reflector and somebody pointed me to Zack Lau's comments in the July 93 QEX where he recommended Techniks, Press-n-Peel Blue. I read the FAQ filled with testimonials and then bought some. I concur--lots of good comments from me concerning PnP Blue. Got some excellent hairpin filters etched. Got traces in between the pins of an IC. Sure, I've had to experiment a bit on temp, time, and pressure, but I am very happy with the product and it puts my mind at ease because I was about to go the photographic process way (and was having trouble getting the positive photo resist).

these following sites were of help to me.

I just ran your numbers through my matching software and yes it shoud
work excellent!

The question remains why you do not get 100 mW out, assuming you mean
300 MHz not milli Herz as then it would be obvious...

Well you run the stage in C maybe try to see what happens when you
increas the drive power, BTW have you tried to bias the transistor?
Apply 0.5-0.6 volts might do the trick. At least it should be eaisier
to drive.

Yes it can be done!
Especially the C84 used to be popped regulary and that is one reason
for bringing the F84 out!.

Not sure exactly how they do it but belive they lower the programming
voltage to 5-6 volt and den erase the chip. Apparently only the
control register is cleared and the program memory is intact. There is
several FAQs describing the way to do it! Search the web and am sure
you will find the information!

Good luck
Cheers

That must be a very small TV indeed. My ARC5 unit would
not support a TV. But then again, my #19 set would.

Nice to see the old gear is still in use.

Tim, take the chip off your shoulder and ignore these stupid comments.
We are smart enough to know that these "snipers" are just looking to get
your goat.

We don't need "road rage" in the newsgroups.

Actually, "Real" hams do go to hamfests to find cheap parts to use for
BUILDING projects. Hams that sit home and work contests are known as
"appliance operators".....

Both McCoy crystal filters are 9mhz and have 2.7khz bandwidth at
6db down. They are new in original boxes with both USB and LSB xtals
supplied. They also have the data sheets.

Golden Guardian has 55db ultimate attenuation. Asking $40 plus shipping.

Silver Sentinal has 40db ultimate attenuation. Asking $35 plus shipping.

Remember, he asked about a single tube transmitter article using a 6L6 or 6AG7, built on wood, using old parts, in CQ or QST. It's true that single tube transmitters were to be found all over the place, but it sounded like he was looking for a particular article.

BTW, with (most of) QST out on CDROM now we can all have a great historic resource at our fingertips.

g'day,
i am trying to make a repeater... i was just wondering if anyone had
any ideas for a home made controller, or even a circuit to just provide
a delay (tail) after the recieve signal dies, to keep the transmit radio
keyed up for a few seconds.... i would like a beep, but it is not
necessary for the moment... also, i'm looking for information about
diplexers/duplexers... what is the difference? i have a diplexer, and
would like to know if it will allow tx and rx on the same antennae at
the same time? also info on tuning the diplexer... it has tuning lugs at
the end... all info appreciated. thanks in advance,
Aaron

I need some help for a friend. He just picked up a FT-73r, and wanted to mod
it so that he could listen to his businesses freq but not x-mit on it. However, the
radio dosen't work much outside of it's designed limits. RX drops off pretty fast. He
says that there's a pot inside that'll widen the radio's RX and TX up. But without
the service manual, figuring out which it is isn't easy. Can anyone help him out?
He dosen't have internet access, nor even a home computer, so I'll relay
messages for him.
P.S., if you think he's doing this to mess around with other freqs, he's most
definately not. He's 67, and he's a Vet who strongly believes in not breaking the
law. I've known him long anough to know that he's straignt. Besides, as a precaution,
he's going to set the Tx freq to something so far out of band that TX power will be 0
watts. With this ht, that's easy.

For sale: about 40 ea. 22 volt, 2.4 amp plastic cased power transformers, with jack for computer type ac line cord (120V 60Hz input). About 4" cubed, 3.5 lbs. each, unused mint condition, $4.00 each or 4/$14 plus UPS. 36330 zip. (Alabama) These could be used with a rectifier and appropriate sized cap to power 28 V filaments, or as is for 21 V or 24 V sweep tube filaments. Also good for 24 V power supply.Email or call 334-347-5281 day/eve.

1810. Re: HELP! Need good 4CX5000 & Socket!

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-08-27 00:00:00 UTC
From: Terry King <tking@together.net>
Message-ID: <VA.00000281.011574d7@together.net>
Source record: 79857

4CX5000's are typically used is FM Broadcast stations of
5000 to 10000 watts transmitter output. Call around to some
'smaller' FM stations and ask how you can contact the
'Chief Engineer' or 'Maintenance Engineer'. You may able to
find someone who will sell a cheap used tube.

A commercial socket will be hundreds of dollars. If he's REALLY talking
about a death-ray HF (3 to 30 Mhz) linear amplifier for AM or SSB
use, he can home-brew a socket with copper strap and hose clamps, and
an insulated baffle to direct the cooling air thru the external anode
cooling fins. He doesn't need the coaxial element properties of the tube
for HF applications. The VHF / FM applications of this tube I've seen in
Broadcast transmitters use concentric finger stock with coil springs and
machined insulators that are pretty complicated.

This is a overkiller of a tube for this application. Getting a filament
transformer for it will be interesting also.

A couple of 4-400a's in parallel (used in MANY 1000 watt AM broadcast
transmitters) would be more reasonable. I used to give a few of THOSE away
to HAMs.

1813. August QST Spectrum Analyser questions

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-08-27 00:00:00 UTC
From: pierre@cmpe.ubc.ca
Message-ID: <6s4ev2$7fr$1@nnrp1.dejanews.com>
Source record: 79860

Hi everyone,

About the August QST Spectrum Analyser...
Web details: http://www.teleport.com/~w7zoi/SA.html

Could I replace the final mixer, the crystal filter and the log detector
by a AD608 and a standard 10.7mhz filter?

Description of the chip:
http://products.analog.com/products/info.asp?product=AD608

This is a chip with an onboard mixer, preamp and log detector as well as a
limiter. Input, -95 to -15 dbm.

I could use a standard 10.7Mhz that I have in my junkbox. This would also
reduce the number of stages. I would not have a choice for a filter
but building it might be simpler. Integrating three boards together.
The Log board, 2nd LO and 2nd mixer board and 10mhz filter board all on one
board.

What is better? A wide crystal filter or a narrow one? (300 khz vs 30 khz)
The 10.7 mhz filter would be around 200-300 khz wide. Anything better?

What about a single conversion scheme with a LO going from 10.7 up?

I know that this is an excellent design (for its cost). How about a
progressive design that could be built part by part and tested progressively.
(similar to a DC receiver becoming a heterodyne by adding stages)

Any good sources for building a stable homebrew wideband linear VCO? Buying
the minicircuit VCO over here is quite expensive. (mainly with the low
canadian looney) I have lots of parts over here just waiting to be put to
good use.

Building a DDS VFO is out of the question because of the digital
part. I want to have a simple interface between a spectrum analyser and my
oscope.

For the timebase, I could use the sawtooth output from my oscope. This
simplifies a bit the design of the sweep genetator(does it?) I could use the
timebase of my oscope to change the scan speed. Any ideas?

Any suggestions/ideas?
Thanks all

T Hwang wrote:
>
> Hi,
> Einstein is turning in his grave!
> Haven't seen a VF >1.0. Some one must have a warped eyes?

I don't know what you mean by VF, but it is common
knowledge that the TE modes in a rectangular
wave guide have a phase velocity greater than
c and a group velocity less than c.

There's really nothing too this as phase velocity
is measured along a reference direction. Out in free
space, if you have a plane wave and you take the
reference direction to be the same as the wave's
direction of propagation, then the phase
velocity and group velocity both equal c.
But if you take the reference direction to be other
than the direction of the wave, then the phase
velocity will be greater than c. Its like the
storm front crossing the road or the scissors
closing.

In a wave guide in a TE mode, there are two
sets of plane waves, both oriented at an
angle to the long axis of the wave guide.
One has a positive angle and the other an equal
magnitude but negative angle. They are bouncing
back and forth from wall to wall, so to speak.
Since they are not going straight down the guide,
obviously group velocity along the axis of
the guide is going to be less than c. But,
the superposition of these two waves creates
a composite field that moves down the guide
with a phase velocity greater than c. This just
means that the apparent motion of the zero crossings
of the field down the axis is greater than c. Just
like the scissors. Think of each half of the
scissors as a plane wave. The are moving with
speed of c. The intersection moves much
faster than the two halves. The intersection
is the phase velocity.

Opinions expressed herein are my own and may not represent those of my employer.

Source record: 79864

Please check the Fall 1996 issue of Communications Quarterly Magazine.
Starting
on page 21 is an article titled: "An IF and 80 dB Log Amplifier for Spectrum
Analyzers".
The design incorporates the AD606 log amp, and gives 80 dB display range.
The IF
uses standard Murata 10.7 MHz harmonic mode ceramic filters. PC boards are
available for the
project from Far Circuits. I designed the unit to easily interface to
Helfrick's 1985 QST
spectrum analyzer design (sold by A&A Engineering).

1820. Manchester demodulator

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-08-27 00:00:00 UTC
From: Luis Yanes <melus@esi.us.es>
Message-ID: <35E5597A.613E@esi.us.es>
Source record: 79867
Cross-posted to: sci.electronics.design,rec.radio.amateur.homebrew

I want to build a manchester demodulator in a FPGA, and I like to find some block diagram or circuit of one that don't use monostables to recover the rx clock reference, but one with a PPL (not PLL) like those high performance decoders the literature talks about. I've looking in some ethernet NIC data sheets, but there isn't much reference to the modem block.

I've seen the S53MV manchester modem design but it needs a 64*clock rate, and it appears that only can decode NRZI signals, not plain NRZ.

Any references or comments to this or related topics will be wellcomed.

Thanks. Luis.

1821. 20-30MHz Linear Phase modulator

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-08-27 00:00:00 UTC
From: Luis Yanes <melus@esi.us.es>
Message-ID: <35E55AE2.62E0@esi.us.es>
Source record: 79868
Cross-posted to: sci.electronics.design,rec.radio.amateur.homebrew

I want to phase modulate a Xtal controlled signal of about 27MHz
with a few hundred Khz width analog signal.

I tried to simulate with spice some phase modulators from the
RSGB VHF/UHF manual (pag. 5.33 fig.67-68) and ARRL handbook,
but with poor results. The one that I found that works is one
with a fet amplifier and a rf bypass cap between gate a drain,
but it looks like this must be tunned with one of the RFC to
the falling slope of the freq response to work, and a high Q.

This circuit is something like this:

```
1mH RFC
-----!!------+-----!!----+---+---UUUUUU-------- +Vcc
RF IN ! ! !
! ! !-----!!----------RF out
! !---- 1n
!------!
C !----
RFC C !-------+
1mH C / !
C \ 2K2 !
!----+ / = 2u
MOD input ! ! \ !
--------------+ = ! !
! ! !
+------+-------+----------- GND
```

I still didn't built any real one, as I like to get some advice
about this, since with the simulaton it I don't get it work
reliable enought, and really don't know if I could modulate
it with 500Khz bandwidth.

Any circuit, reference or further theory about phase modulation
at this frecs, will be wellcomed.

Thanks. Luis.

Hello All,

I am posting this for a friend. He wants to know how to connect his
Collins 30S1 (stand up model) linear amplifier to a Kenwood TS-850.
Would the 850 have enough drive for the Collins 30S1?
Also, where can he get replacement parts for the 30S1?
Any advice most welcomed.

Thanks,
John Strunck III

What to put into my cantenna has been a question before me for a while, so this one interests me.

I've heard everything but ketchup suggested so far, but I wonder--what about DI water? Non-conductive, good heat transfer properties and low viscosity. I suppose the drawback would be that if air becomes dissolved in it, it can be a bit corrosive and could rust your can and other innards. Maybe deaerate it first and put a layer of oil on top to keep air from it.

How crazy does that sound?

I would worry that any oil that is corrosive or contains
detergents might possibly damage the resistive unit, let alone
the can.

Mineral oil. Mineral oil. Mineral oil.

Hi, all
I looked for some free or cheap programs to make PC board layouts.
I downloaded Eagle Lite from cadsoft, and also Protels freeware program
called Easytrax. I would like to know if anyone can tell me their
experiences with either or both of these programs. I would like to try
to select the best one before I commence learning the software. Thanks
for any opinions on the subject.
Don

A SAW resonator can fabricated using sub micron photolith for resonance
above 1GHz, normal crystal processing with overtone (not multiplication)
operation gets you to 5 times 30MHz ie 150MHz new technology ion beam
etching or chemical etch yields 150MHz fundementals from various
manufacturers.
Basically fundemental oscillation with 100ppm tempco in the range 0.400
to 1.4GHz is not possible by other means, youve got to use a PLL or
multiplier with power and size penalty.
When there is a high volume low power low cost over 400MHz at one
frequency and the specs are not too difficult SAWs are used until
dilectric resonators with inferior TC take over.
Doug.

If you really want to QRM the illegal CB operators it is better to sweep
10M band, they left 27MHz long time ago!

seems to be some sort of miller capacitor effect between gate and drain
of a fet. I used similar narrowband modulator 30 years ago using bipolar
transistor Motorola MPS3394 (=BC547/2N3904) with a few mA collector
current. A FET may have quite low gain in this application. On the
desired frequency the capacitor may be quite small.
In my circuit I used 8MHz, I believe I used 50pF for 5kHz deviation and
resistor to +Vcc. PM sounds like FM with 6dB pre-emphasis per octave
If you wish to have 'real FM' you must integrate the modulating signal.

By the way, 27MHz xtals are bargain for use with some amateur radio
bands, operated on 5th overtone it will run in 45MHz RX-LO, 16x27=432MHz
48x27MHz=1296MHz.......

In some German LO's a 27MHz xtals are run on 81MHz, 9th overtone
I'll be pleased to find a source for cheap 27MHz xtals to save cost of
several projects.

Hello Jim,

Looked-up the 455 in the Motorola databook, hoping for a gain/freq curve. No luck... All specs are at 30Mhz. You didn't mention if this was for linear service or not, but all specs were for class C operation. I have biased similar devices for (sorta) linear operation. Biased linearity was not as good as newer devices, but was servicable for SSB. ...I tried similar at UHF for ATV - forget it! For linear op, the power will need to be derated. With an increase in frequency, the disipation should be ok, but the gain will drop. It is rated at 13 db at 30 Mhz....

> Torvald Lundberg / SM2EZT

I am building a similar amp, but with 16 MRF150's.

Considering that you will be getting 600W key down at the
ratings of the transistors, which is nearly 4 Amps at 50 ohms,
you need to measure the contact resistance of the candidate relay
of calculate the heating involved. Or just put 4 Amps of DC thru
the relay and see what happens. Not doing hot switching is a
plus, but I would be nervous about putting 4 times the rated
current throught the relay, especially since the power dissipation
is increased 16X.

I am building a 50 V 80 A supply. One of the benefits of
regulation is that you can use smaller filter capacitors, which
decreases ripple current and rectifier dissipation. The hardest
part to get for the supply is the transformer. I finally found
a 95 lb one that should be good enough to get by on. It would
have been easier at your reduced current drain.

Having read your question and some of the other posts, I have two questions:

1. have you checked with the phone company to see if they already have
something that will work?
2. have you considered using an acoustical coupler instead of a direct
connection?

For a direct connection, a hybrid coupler would be ideal, but by whatever means, isolate the computer from the phone line. Then, with a small value limiting resistor in the output line, back to back zeners could be used to chop off the ring voltage peaks to the sound card. If you are unsure what to do, get assistance locally or ask more questions. It is not easy to tell your level of expertise with the little I can glean from your posting. I get the impression that you know some basic electronics, but don't have working knowledge of the phone system. There are some telephone interface circuits that have been published in magazines that would work. Check your local library for more ideas.

Someone in this thread mentioned post-WWII dumpster diving! Boy, what memories.

On Saturday we would ride our bikes out to the garbage dump on the river bank and scrounge for old radios to get tubes, wire, and other parts. Back then, a lot of homebrewing centered around what you happened to find.

One time a friend came up with a 117GT7 (or something like that) which was a single envelope half-wave rectifier and a power pentode that used a 117V filament. Viola .... the half-wave rectifier became a power supply and the pentode a 1 W tritett oscillator. There was no line isolation in the power supply and when my friend showed up at a ham club meeeting to demonstrate his wonderful invention he plugged it in wrong and had 117 VAC at chassis. Unfortunately, there was a concrete floor and he was knocked for a loop when he tried to connect the thing to the club 80M antenna!

We seemed to learn a lot of theory back in those days by making mistakes like that! As for frying crystals, they were so cheap after the war that nearly everyone had a cigar box full to be swapped like baseball cards! I think it was a #47 or #51 dial lamp that was used, though, to protect the xtals in some rigs.

I am trying to preprogram a display's offset but the counter ICs are strange
and cant find in my IC data books. The displays are NIXIE and each driver board are on individual small PC boards. The freq counter is a WJ/CEI dro-307-1.

Anyway the ICs have these numbers on 'em and would appreciate any ref pinouts, crosses, etc...

Email I received Regarding this controller, Sorry but I cannot remember the URL, but this will help you find it.

Pretty attractive controller.

This is the ordering information you requested from the AP4800 Web Page.

The model AP4800 is a repeater controller with a phone autopatch that is controlled by DTMF tones. It uses the Intel 8749 microcontroller (Intel is a registered trademark of Intel Corporation). A complete repeater can be made by connecting a receiver, transmitter, antenna system, 12 volt power supply and a phone line. No other add on boards are needed. The antenna system can be two separate antennas or one antenna with a duplexer.

Features:
• DTMF Controlled Autopatch and control lines.
• Selectable rejection of long distance calls.
• Four control outputs, open collector 30 v max, 40ma max.
• Four LED's for POWER, TRANSMIT, RECEIVE and PHONE.
• 15 DTMF selectable courtesy tones controlled by an input line that can be used to detect power failure (running on batteries) or connected to one of the four control outputs or a jumper.
• CW identification every 8 or 9 minutes while active and waits for user to unkey before sending.
• CW identification call sign is switch selectable (you don't have to have it reprogrammed).
• DTMF programmable timeout during normal repeater operation.
• DTMF programmable timeout during autopatch operation.
• Power requirements: 11 to 15 volts at 250ma.
• Only one level pot to set TX audio level.
• Control line status report (one beep=off, two beeps=on).
• DTMF Reset of the MPU in case it crashes (lightning can crash an MPU).
• 8749 single chip microcontroller.
• All connections are mini screw terminals.
• Fits into Radio Shack plastic box #270-224 or JDR Microdevices metal box #3125C.

Any one of the four control lines can be connected to the long distance phone call reject input. When control DTMF codes are received two beeps are sent for acknowledgment. When the autopatch is turned on a dial tone is sent for acknowledgment, then the phone number is entered. When the call is complete press the "#" key, and the repeater

will go back to normal operation.

Timeout of the repeater is acknowledged by two low tones when the user unkeys (similar to the tones heard on video games for "game over" or on game shows for the "wrong answer"). Timeout of the autopatch is acknowledged by the normal courtesy tone of the repeater.

Long distance calls are rejected by detecting the first digit of the phone number. If it is a "1" and the reject input is high then the call will be rejected.

Connections via the sixteen (16) mini screw terminals:
1 Power Ground
2 Power +11 to +15 volts regulated 250ma max. (130ma typ.)
3 Receive Audio Ground
4 Receive Audio (2.2 volts Peak to Peak or .77 volts RMS)
5 Receive COS (pull low when receiving)
6 Transmitter Ground
7 Transmitter Audio
8 Transmitter PTT (open collector output goes low for TX)
9 Phone Line
10 Phone line
11 Control output 1 (open collector low active)
12 Control output 2 (open collector low active)
13 Control output 3 (open collector low active)
14 Control output 4 (open collector low active)
15 Ground for Control outputs
16 Used for linking (goes low during CWID)

The board is high quality Glass Epoxy double sided with plated through holes, solder mask on both sides, parts legend on top side and wave soldered.

Answers to Frequently Asked Questions

1. The CWID sends the callsign set on the DIP switches and adds "/R".

2. The Autopatch does not regenerate the DTMF digits for the phone number, the tones from the users radio are sent directly to the phone line. The phone line must be a "Touch Tone" and not a "Pulse only" type.

3. This controller was designed to be low cost with an autopatch all on one board. It was designed for one receiver, one transmitter and one phone line. It wasn't designed for remote base, linking, simplex autopatch etc. Some of my Hi-Tech customers have added more receivers and transmitters with additional circuitry. You could have 3 receivers and 3 transmitters (2m, 1.25m, 70cm) all controlled by one controller but that is up to you to figure out.

4. The autopatch doesn't have a ring detector and won't do reverse autopatch.

5. The CWID waits for you to un-key for up to 60 seconds. The CWID is
not sent during idle times. The CWID is sent after the first key-up
and then every 8 or 9 minutes after un-key.

+11 to +15 volts at 250ma max. My tests show that the typical power
is about 130ma at idle and about 170ma with the autopatch active.

Power on reset:
When the power is first turned on the repeater controller will send
the CWID (Continuous Wave Identification) and then go into it's idle
mode and wait for a signal from the receiver. All of the open
collector outputs will be off (high).
Hold any DTMF key down for 10 seconds = MPU Reset (same as Power on
reset).

CWID Setup:
Your call sign is programed into the controller by a set of six DIP
switches. A "/R" is sent after your callsign. Each DIP switch has
six switches

FOR ORDERS:
Check or Money order for $160 to -

SCOTT RUMMINGS
6865 LAKE ROAD
PRINCE GEORGE, VA 23875

The AP4800 is currently in stock.

There will be a delay for checks to clear. Orders paid by money order
will be shipped as soon as possible.

Source record: 79731

Just in case you haven't, it is because there is no such thing as 73s. The term "73" means best regards. Therefore, "73s" means best regardses! By using the terms "73s", "73rds" or "73's" you are showing your ignorance. I know that some of you feel it is correct to say "73s" to a group. But, I submit that such usage probably gave root to the use of the incorrect plural form in the first place. So, just say "73 to all" - it really isn't that difficult to use these terms correctly!!

Thus, the reason "73 Magazine" was so named is because "73" is the correct form of the term and even Wayne Green knew that way back when . . .

Now, while I am on the subject, what the f--- is a "guide wire" or a "guyed wire"???? Since both are incorrect, I don't have any idea how to spell it/them! Additionally, how do you think this got started? It's kinda like using a term that was popular (among those who were just ignorant enough to use it) back in the Eighties - "satellite disk." By definition, a disk is flat not parabolic. Kinda hard to focus something when the focal length is infinite!!! By the way, you support (or guy) a tower with guy wires . . . not guide or guyed wires.

The point of all this is to demonstrate how our hobby has been bastardized by a bunch of ignorant smucks. I want to take it back. From this day forward I will correct anyone I see or hear using incorrect versions of "73" - I will do so politely but firmly. Will you do the same?

It's pretty easy to do if you have a 10x or 16x clock and logic
that can easily run at that rate.

It's just a state machine. There is one bit of input - the data
sample. There are 2 outputs - the data bit and a clock enable (or
data valid). You might want a carrier out too if you are decoding
something like Ethernet. The internal state is 1 bit to remember
the data sample on the previous bit and 3-5 bits to count ticks
since the start of the last bit-cell. (The number depends upon
the clock rate.)

You can probably work things out by playing with paper and pencil
for a while. Graph paper helps.

Hello de K4YZ

Although it wasn't 1 tube, my first TX as a Novice was a 3 tube rig built from either the 69 or 70 Handbook.

It used a 6146 as a combined oscillator and PA, and an OB2 in the power supply. It covered 80 and 40 meters very nicely with 36 watts out on 80. I forget what the 3rd tube was off hand.

It was a nice little package and went together in about a day and a half, not counting the time it took me to drill holes in the chassis, etc!

Am now working on a "nostalgia" station...a tube TX with 35 watts out on 80 & 40 (VFO this time!) and a tube receiver. Am even thinking of making my own ladder-line, but I'm not THAT ambitious!

Distilled water would be OK for a dummy load as low as 50 ohms.

But because the dielectric constant of water is about 80, the stray capacitance associated with the resistor elements would increase by 80 times. This would make a mess of the high-frequency response.

But good try !

If you just want to interfere with the whole of the CB
spectrum all at once, then phase modulation is the hard way. Simply
amplitude modulate a carrier near the center of the band with a fast
rise-time square wave with a frequency of about 1/5th the channel
spacing.

DAA (data access arrangement) is well-documented and you should be
working from this standard if you're connecting any digital device
to the PSTN.

Hello, Spike ....

This is an excellant and informative site for the active ham. I
strongly suggest all to "bookmark". Gee, all you need now is the latest
24 hour forcast for band conditions from WWV at 18 minutes after each
hour.

Good job es 73!

A DPST relay that only gets turned on *after* a call is in
progress would be nearly 100% effective. The phone can't ring while
it's in use.

Tiny relays that work on 5 volts are cheap too.

Hello, folks!

Well, after being an idle ham for years and years, I've decided to build my own station. I'm a novice, so I'm looking for suppliers for GOOD cw rig kits. I don't mind spending a little money if I can get a kit which is well documented and has excellent performance specs, especially in the receive department.

Any ideas?

Thank you very much for your help!

If you don't need to detect the rings, then use a relay to connect a
600:600 xformer primary to the phone line and pass the secondary thru the
rest of your circuit. When you aren't talking on the line, leave the relay
open. Use a DPDT unit to disconnect both leads of the primary. (Or use a
toggle switch...)

Do you have a design for the rest of your audio front end?

Nick,

One of the problems with water is its low boiling point. That will severely limit the amount of power you can dissipate. Another is that if anything dissolves in it that ionizes, water is no longer nonconductive.

That's "shmucks".

Of course you're right: how can we communicate effectively if we're not using the same dictionary. But my brother (isn't there always one in the family) would argue: "Language is descriptive, not prescriptive," which I've always had a hard time countering. A dictionary will change a definition of a word (or add new ones) based on its appearance in the language.

Start looking for "satellite disk" soon, in a dictionary near you.

Source record: 79758

Hello Rick,
I use the book RF Circuit Design.
There is is a simple but good explonation of how to make LP-filters.

The filter you hav shown is a 3'rd order Low Pass filter.
It could be of different types depending on your need.

The values depend on your input and output impedance, cuttoff frequency
and type of filter.
The moust common filter designs are Butterworth and Chebyshev. (there
are a lot more)
The butterwort filter have flat passband and no ripple but not the best
steepness.

To calculate a LP filter with the same input and output impedance with
Butterworth responce do as follow.

L1= R/(pi*fc)
C1 = C2 = 1/(2*pi*fc*R)

where
pi=3.14159...
fc= cuttof frequency in Hz
R= input impedance in Ohms

The result is in Henry and Farad.

Example: fc=10 MHz and R=50Ohm gives L1=1.59uH and C=318pF

Thanks for the replys, all.

I'll provide a few more details and clarify my intentions, here.

This circuit is for the purpose of providing my mother, who has lost the ability to speak, with a means to carry on a phone conversation with someone who she calls, or who calls her. The laptop has the ability for text-to-speech; whatever she types will be spoken.

I want to connect a cable from the analog audio output to the telephone line permenantly (well, at least not have to plug and unplug it for each use). If I understand correctly, a hi-impedance transformer primary won't trip the CO connection. This permenant connection is just for convenience.

When I lift the telephone receiver on that line, the CO connection will be established and I can dial the phone number. I can then, during the conversation, add output from the laptop's audio output to the conversation.

I've been told that all modem circuits must handle ringing voltages. Do they disconnect from the CO line with a relay, or do they handle ringing voltages other ways?

Regarding the rest of the circuit: I wasn't planning on anything but a transformer-- hi-Z (10K?) primary, lo-Z (1K?) secondary-- connected

directly to audio output and to the phone line (with ringing voltage components between CO line and primary).

Any suggestions welcome and appreciated.

Thanks,
Dave

Hi,

I'm looking for a good 2m receiver starter kit. I was thinking of the mfj-8400k. Does anyone have any experience with this kit? And what would a good place to buy it? (boy did I just open myself up for some spam :)) What I'm basically looking for is a relatively simple 2m FM receiver, which preferably can be extended later on with AM/SSB/CW etc.. Maybe there are other kits out there that I don't know about and might be better than the one I just mentioned.

Your advise is appreciated!

Luis,

Find a cheap, 30 dollar 40 channel CB radio.

They all use a PLL to determine their frequency
these days.

Apply your analog signal in a resistive summer
with the PLL output correction voltage to the
varactor diode the radio uses in it's voltage
controlled oscillator circuit. Or simply
capacitively couple it if the frequency response
does not have to go down to really low
frequencies.

Set the channel selector on channel 20
(27.205MHZ), and you should easily be able to
sweep up and down a few hundred kilocycles, while
still maintaining crystal-controlled center
frequency stability!

Remember to use a padder to reduce your output to
100 milliwatts or less or you will completely wipe
out the local CB band! (Now you have some idea how
I know this trick works!)

If you need higher power output than 100
Milliwatts, then it would probably be best to
change (lower) the PLL divide ratio to put the
transmission up into a higher frequency, but
unless you get some kind of special permission
from the FCC, the only place you could put it is
on 10 Meters and then only if you had the proper

HAM license!

If you just want to send the signal on an
Ethernet or 10 base T cable system then there
would be no license required, but the network
administrator would go NUTS!

Two that always confuse me are: "Transistor" when the meaning is not the individual device, but a collection of same usually called a radio - and "Stereo" again describing the whole kaboodle, rather than just one of its characteristics.

>
> Jim

Jim,

Unfortunately, the waveform would not come out as
a square wave as it would be 'shaped' by the audio
bandpass limits and also by the modulation
transformer, and would be even further 'modified'
by the AMC circuitry in a 'stock' radio. I
understand what you are trying to do, but to get a
'comb effect' at every 2 kHz you would probably
have to DIRECTLY modulate the driver and final
with that fast rise time squarewave.

What you suggest may be easier to do in some of
the SSB CB sets that use a series regulator
transistor to amplitude modulate the carrier by
varying the collector voltage to the driver and
final.
But once again the audio bandpass would defeat
you unless you could bypass the audio circuitry
and drive the series pass device directly....

It's actually easier and more effective to FM
sweep through all of the 40 channels at a low
frequency audio rate and let the receiving radios
IF strip 'slope detect' the FM signal. The
resultant tone will appear exactly the same on all
40 channels and be at the maximum possible audio
output level possible as detected by the IF and

feed into the audio volume control circuitry. An additional advantage of using the FM sweep method is that if properly done, it will not interfere with any of your neighbor's TV sets or any other of their electronic equipment...

On the question of what type of oil to use for a dummy load, about three years ago, I built the "Super Dummy" which is essentially a two-story version of the Cantenna, using two one-gallon paint cans which are modified to make a two gallon container. It uses a larger version of the 50 ohm N.I. resistor used in the Cantenna. The contruction details for this device are in the 1990 ARRL Handbook for sure, and probably in other edtions as well.

The oil they recommend in the article is a type of heat transfer oil called "turbine oil". It is chiefly mineral oil, but with special anti-oxidant and anti-corrosion additives. The brand mentioned in the article was sold by Texaco under the name:

Regal Oil R&O No. 46

The oil I bought locally is called:

Galaxy Oil R&O No. 46

It will probably be necessary to buy a five gallon container of the oil, but in a call to the local supplier today, I was quoted $3.27 a gallon for the five-gallon container, including the (plastic) container itself.

The "Super Dummy" works quite well. I can load 800 to 1000 watts of RF into it for a minute or so continuous, and only notice a small amount of warming above the submerged resistor. Try that with a Cantenna and you'll be ready to put in the french fries! The Handbook

article has good info on what <<not>> to use for the oil, and is a good read even if you don't want to build the dummy load.

Good luck,

Barry Redenbo K9YUG

Yep, a cool site indeed, and you can get those latest WWV reports and much
more with ABW++, available from URL below.

If you are referring to AO-27, I have had little or no
success working anyone via it due to it being swamped.
On top of that, even with my directional antenna and preamp it is still
barely audible.

You're right, it's often a mob scene on weekends, especially on the trans-
continental passes. I suspect it requires a different set of skills to work
effectively than most of the other birds. It's easier to hear outside of
urbanized areas, by the way.

After working AO-27 for about a year, i got an Alinco DJ-G5TH and have been
able to hear it (and work it) with a long rubber duck. But i cheat a little,
given i always use a chain link fence or other large vertical metal object
as a reflector, and folks on there already know me. That mode of operation
is NOT for beginners!

antennae. Now we have both FO-20 and FO-29 operating in analog
mode continuously. They are relatively easy to work, if you have
the equipment. I managed to get a few dits through AO-10, but 10 watts

I'll have to see if i can hear them with my homebrew 2m/70cm antenna, which
let me work AO-27 comfortably with an HT (i've been primarily operating
satellite mobile so far). I was able to copy K6AKO (SSB) last night with
the DJ-G5T (in AM mode), so that's a decent nudge for me to get ready for
SEDSAT.

I agree that all-mode equipment for 2m and particularly 70cm is
not cheap. Once I caught the satellite bug it took me a couple
of years to acquire used all-mode gear at a reasonable price.

...

Erik van Bronkhorst
kc6uut@qsl.net

I've got 6m QRP SSB, so maybe an asymmetric transverter (10M -> 6M -> 2M)
might do it for me. Has anyone tried such an approach? Given separate
feedlines (not unreasonable at 10m), that has the nice property of not
requiring antenna switching (and with a suitable antenna, i may be able
to do without an elevator). Hmmmm, if the LO for the converters were
varistor VXOs, i could probably use a pair of DACs and a laptop/palmtop
to supply doppler compensation...

Consider trying FO20 or FO29. They are mode JA (145 up/ 435 down), the
same transmit uplink as mode KA was, and can be worked without
high-gain antennas.

Rick Tannehill - W7RT

Later i can think about a downconverter from 70cm, after i have developed some RF construction skills... I'll see what i can hear next time they come over when i have my LPVA with me (as it resides in my office on weekdays).

But meanwhile, AO-27 keeps me pretty busy. But it would be nice to able do something vaguely resembling a decently long QSO, as anything vaguely close to ragchewing is out of the question on AO-27 (except on rather rare occasions, like a weekday Pacific pass when Hawaii hasn't been heard for awhile).

>

I'd start with building a little box with a DPDT toggle which isolates the
xformer from the line. Your mother then clicks it on to connect, puts the
phone on hook- then concludes the conversation by turning off the toggle.

I think other posters are right to use a 8:1000 transformer to get
something approximating a matching impedance. The 1k side should put
enough DC load on the phone line to keep it off hook during the
conversation. If not, you could introduce a resistor across the 1k winding
to increase the DC load.

I'd also put a series pot on the 8ohm side to allow you to adjust the
volume going out on the phone line.

All illegal of course...

I have a matched pair of MRF-455 transistors I'd like to use for a six meter amp. I realize that these transistors are rated for 30mhz, but my question is if they can be used for 50mhz at lower power levels. I'm trying to build this amp for minimum $ using parts on hand.

Thanks,
Jim KB9RQD

I would buy an old modem and splice into the telephone line interface
circuit. You might even be able to use the ring detector circuitry to
do something useful.

In the USofA you can connect anything you want to the
telephone lines inside your own residence. It might be illegal to put
enough voltage on there to kill somebody or start a fire in the
central office, but there are no "phone police" going around examining
all the equipment connected to the phone lines to see if they meet
some specification. If you connect something up that makes trouble
for the phone company, they have the right to disconnect your service
until you get rid of it. If you want to connect something that makes
your service unsatisfactory without causing other subscribers any
harm, you're completely within your legal rights to do that.

What you're probably thinking about is *selling* telephone
equipment that doesn't conform to proper standards. That's a
different matter altogether.

Seeing as how the majority of your country stays frozen most of the year, maybe we can open an "ice" crystal factory. You could use the little crystal heater ovens like a VFO to shift frequency, but only one time. Just kidding - don't puck me with a slapshot, heh. Plenty of South Of The Border xtal folks to meet your needs, but when I say SOB, that means they've (like every other mfgr) all left here for Mexico, but at 65c to the dollar, they may be coming your way soon.

16 MRF15's Wow!
I found that cheap welding transformers have the right Volatage and power
ratings.
They also have a adjustable magnetic shunt that will give redused current.
I will test the transformer today to see if it works.
I think will try with 7 A rated relays.

Than you Richard and all the others that ansverd via e-mail.

From: ku4qw@my-dejanews.com
Message-ID: <6s9a7d$o4h$1@nnrp1.dejanews.com>
Source record: 79698

Hello All,
I'm wanting to start making a few of my own circuit boards, so I have a few questions.
Where is a good place to get single sided board, does it come in stock sheets, about how much does it cost?
Also I was just wondering, from the little boards that I got at Radio Shack, how do you cut the board? I know I've seen some like cut for a tuna can, or for a sardine or >>>SPAM<<< can?
Is the stuff you buy at radio shack ok to use to etch, the PCB Etchant Solution? Any hints on it's use, I never could get it to work that well.
Thanks for any and all help/suggestions/comments

1900. Inductance of resistors ?

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-08-29 00:00:00 UTC
From: Don <bjmcpher@usit.net>
Message-ID: <35E85B50.28F266ED@usit.net>
Source record: 79699

Hi all,
I've been trying to find some data on the reactance of resistors.
(1/4w and 1/2w, carbon film and very particularly METAL film). I've
searched a bunch of mfg's web sites with no luck. I did read in the
Handbook that the metal film types are sometimes wound in a helix and
have much inductance. They didnt give data, nor mention if this was true
for some range of resistance like very high values. If anyone has any
Ideas, data, or guesses, I would appreciate it.

Don

When on SSB/FM/AM, wouldn't it be better to say 'best regards' rather
than 73?

There's fewer syllables, and non-hams listening are not perplexed by the
jargon.

73 has its place for CW operating, RTTY & e-mail (as it is shorter), but
it's probably superflous for most phone contacts.

73,

Why not connect a small speaker to your computer audio output and place it
near the microphone of a speakerphone. This way your mother can type and
listen to the phone party on the speakerphone.

> F 996079
> F 820
> SIG N8280A

IIRC the F 996079 devices were from Fairchild's old "counting micrologic"
(or CuL, where u="mu") series, which was an RTL family intended for use in
counters. The first four digits denote the device type, which in this case
would be 9960 - again IIRC the 9960 was a decoder/driver device. Your
third device listed, F 820, seems to be an incomplete (or very very old)
part number at least for a Fairchild digital device. Your fourth device is
a Signetics N8280, which according to a colleagues' June 1972 Fairchild TTL
data book is a pin for pin equivalent to a 93176 or 74176 BCD Decade
Counter.

(after a few more minutes of scouring the Fairchild data book...)

It does look like I was correct in my recollection of the 9960; section 12
of this old data book does indeed list the 9960 as a decoder/driver device
in the CuL family. Unfortunately, it gives no further data on the device
(sigh). I do know of a '60s vintage Fairchild data book which ought to
have info on the 9960, unfortunately it's ~900 miles away (sigh).

Well, I hope this helps a bit...if I can get someone at the offsite
location to find the old data book & lookup the 9960, I'll do a followup.
However there's a chance that the data book got purged :-(.

Good luck -

TGB

I get my PCB material from Digi-Key, they have 12"x12" sheets.
I think they are about $17.00.
I use a band saw to cut the boards. you can scribe them deep with a
sharp knife and snap them. I use the radio shack etchant, and I've had
my problems with it, but haven't found anything better. Sometimes it
takes 20 minutes and sometimes 55 minutes for the same layout.

Source record: 79706

I am curious .... why is the inductive reactance of a resistor of interest? I never even thought of a resistor having inductance (or capacitance) until I read your post.

You know if we baked bread to the tolerances we build electonic gear, we would all starve to death. Imagine a loaf of bread being put together with a plus or minus 1/5 (20%) tolerance on flour, milk, yeast, and baking time!

But to answer your question, check out the MIL specs to which the resistor is built. Somewhere in fine print you will find the reactance!

You could go inside the phone instrument and make your connections after the switch-hook. That way there will never be any ringing voltage applied to the computer. When the phone is on-hook the computer is disconnected. When the phone is off-hook the computer is connected but the phone can't ring.

Without some kind of current limiting resistors this will place a heavy load on the line during ringing as the diodes conduct and effectivly short the line. It probably will keep the instruments on line from ringing.

I am curious .... why is the inductive reactance of a resistor of
interest? I never even thought of a resistor having inductance (or
capacitance) until I read your post.

If the resistor is used in a RF circuit, the inductance can have an effect
on the circuit's operation as the resistor is no longer purely resistive,
but inductive as well. Small values of L are of little significance at low
frequencies, like audio, but can play havok at RF as inductive reactance
increases proportional to frequency.

Some resistors, such as wirewound power resistors, can be quite inductive
and are used primarily for DC applications. I've made low value resistors
to use as meter shunts by winding lengths of wire around an insulated core-I
used teflon rod because I had it, but others have wound them around
high-value resistors. The DC resistance is a fraction of an ohm, yet the
inductive reactance would be pretty significant at RF.

Hope this helps. Have fun!

Some years ago, when modems were just beginning to become common, the telephone companies permitted connection to their lines only through a telco-supplied interface unit. (Knowing Ma Bell, I'm sure they had a strange name for these -- perhaps someone else recalls exactly what they were officially called.) This box limited the amplitude and frequency range of the signals reaching the line, and whatever else was necessary to make sure the connection conformed to teleco standards. I don't know what sort of conditioning was done to the signal from the line back to the user, but it may have stripped or limited the ringing voltage. You might see if these units are still available, and whether one might be a solution for your problem. It should at least relieve any possible concern about your applying damaging signals to the line.

Hi Torvald,

I'm in the process of building a 50V 45 Amp supply. It is currently working, but needs some final touches. I use a pretty big transformer at 240V and 54V RMS secondary. I use 5x33000microF capacitors. The regulation is done with an LM783 which is the only regulator that seens to handle this voltage. This regulator drives a 2n3773 emitter follower into 6x2n3773 pass transistors. Currently I am regulating to the output of the first driver. This means that the 6 pass transistors are not regulated. I get less than 2 volts Vbe drop when I key the amplifier at full power. If you have any other questions let me know. I have some amp and supply pictures at:

http://www.ibelings.com/n4ip/mrf157.html

I remember them, Roy. They had a transformer, limiting resistors, back-to-back diodes to limit the level of signal you could put on the line, and a notch filter to remove frequencies that could fall into their signaling band. My experience with them was that they didn't make your signal sound very good and limited the level too low. The result was that we skipped the legalities and made our own interface.

Hi guys,

I've obtained an old 27Mhz CB which I'm going to convert to 10M FM.
I'll have to get it working first! The final transistor, a 2SC2078, is
dead. I can't find this listed in my catalogue. Does anybody know the
direct equivalent to this? Possibly and MRF or 2N number?

Any help appreciated.

I have seen a few Boonton 42 series RF Microwatter meters for
sale cheap. I would like to buy one, but most are missing the
optional RF power heads. Can anyone advise me what the
head contains for parts, and whether it is feasible to homebrew the
head assembly for these units? Has anyone in the group done
so?

Regards

Peter

Carbon composition resistors, especially 2 W types, have a lot of shunt capacitance that can be a problem at 30 MHz in certain applications, for example in an RF voltage divider. I have verified this, using my vector impedance meter. I find that using several lower-wattage resistors in series greatly reduces this problem.

Source record: 79650

Type "ICN"

New in Original Box!

With Instruction sheet and mounting template.

Gorgeous 7" X 5" black crinkle finish dial plate,
half moon shaped 5 scale plus logging dial,
"Velvet Vernier" reduction drive and original knob.
(Can easily be back lit.)
$40 Shipped in CONUS.

Thanks,

Dave
w2qa@execpc.com
(608) 836-7783

PS I also have some other types of Velvet Vernier
dials as well as National parts, but not all new.

For 150 or 200 dollars you should be able to find a fully solid state
modern scope on the surplus market. Tek 465M military scopes,
dual trace, 100 MHz have been going for as low as 300 dollars.
Don't waste your money on a 1950s vintage tube oscilloscope!
Check the dealers listed in the Nuts n Volts magazine.

If you have the computer interface, it's super easy. I write and maintain the faq on how to do the software modifications. The cool thing about the software modification is that it dosen't erase your existing freqs.
I just learned that if you have a newer FT-50 and set the radio to FreeBand mode, you'll hose it up good! So, don't do it, if you want freeband, get a used one and mod that. I don't know if you can set the newer radios to Canadian mode to at least get cell RX though.
BTW, if you do do these mods, can you tell me what country code your radio uses before modification? Just to add this info to the faq.

You can find the faq here:

>or what is the problem ?

Eric,

To convert normalized impedance to reflection coefficient use:

Gamma = (Z-1)/Z+1)

For your example this gives: Gamma = 0.2 +j0.4

Expressing this in polar form: Gamma = 0.447 < 63.435 deg.

Don;
If I remember correctly the lead inductance for most 1/4 w and 1/2 w film and carbon reistors is about 4 nH per inch. This inductance does not become a major problem until arround 400 Mhz. If you are working at HF frequencoies or even 6 M band then the lead inductance is of little importance. At 2 M and above some care is needed. By the UHF band and above it is critical. The self resonace of most leaded resistors is well above 800 MHz. The exception to this would be the wirewound reistors. They should be used in power supplies or non RF circuits only.

Hope this helps

Regards
James

You can search for upcoming hamfests, based on various criteria, at the
Radio Amateurs of Canada website at http://www.rac.ca I don't have the
URL for the specific section, but it's not hard to find. If you're lucky,
you haven't missed all the local hamfests for the year.

The ARRL also has a listing of upcoming hamfests, though it seems to
be just a list by date. http://www.arrl.org If the hamfest organizers
are doing a good job, both sites should have exactly the same hamfests
listed.

There's a place that advertises in the advertising section of Electronics
Now, and it's located in Toronto or thereabouts. They sell surplus radio
and test equipment, and I've seen oscilliscopes listed in their ads. I'm
not sure about the prices though.

There's a great surplus store in Toronto, Active Surplus Annex, on Queen
Street West. It's been years sicne I've been there, and I don't recall
any scopes, but it might be a place to check out.

You might also try posting in a local newsgroup, I think the Toronto
hierarchy is tor.* Find the forsale newsgroup, and post a message.
You just might get someone's attention who has an old boatanchor scope
lying around and would be glad to give it away.

If you go to the RAC site above, I think there's a list of ham clubs
across Canada. Find the list, and contact them. If they have a
newsletter, there mgiht be a place to put an ad.

I got a Tektronix 545A with various plug-ins (it's a few months older
than I am) a few years ago when a friend of a friend found one in the
garbage at a hospital. Yes, it's heavy and big and uses lots of current
because of the tubes, but it was free and I'm not sure I'd have a scope
without it. I wouldn't spend much on something that old, but it is still
a useful scope.

Right, this is exactly what I was reffering to. If a spiral groove is cut, then an inductance (in addition to lead inductance) is created. I'm looking to find out at what resistance value can one expect to see this type of configuration? and what inductances are to be expected. I'm hoping the answer is that it is only done for very high values, say on the order of 10k or more.

Hi Don,

according to Eric T. Red's "HF-Arbeitsbuch" with typical non helix resistors (< 1W) from 1 Ohm to 150 Ohms the parasitic inductive component dominates. The inductive component decreases from approx. 0.5 uH @ 1 Ohm to nearly 0 @ 150 Ohms. Above 150 Ohms there is an increasing parasitic capacitive component (approx. 5 pF @ 10 kOhms).

The best choice for RF frequencies and above seem to be chip resistors. A 22 Ohms 0805 chip resistor for instance has a parasitic inductance of 0.8 nH.

Hi Dave,

I just look at a book from Motorola. It says :
1) The formula Rout = Sqr(Vcc - Vcesat) / (2 x Po) is not very accurate at high frequency.
2) Vcesat is often about 2 or 3V.
Further more...
3) I try some computations for many devices where Motorola gives Rout and it is equal between 30% and 120% of the computing value with the formula in 1) !!!
4) At high frequency Rout is lower than at low frequency.

73's de Eric / F5MSL.

Allan, I think my last posting to a similar question of yours a while back just discussed alternative antennas without emphasis on the possible consequences of their use w/ an HP 117A; if it seems like my previous post might have led you astray, I'm sorry.

The 3 Hz bandwidth discussed in Don Lancaster's 1973 WWVB articles in Radio-Electronics pertains to the bandwidth needed to recover the time code information in the WWVB signal - that was the main thrust to his articles, i.e., how to receive, decode & display WWVB time information. I don't have the articles handy, but IIRC Lancaster discussed some design tradeoffs on how to get to an equivalent received 3 Hz bandwidth in a cost effective manner. You'll also note that he mentions in passing an approach to building a frequency standard locked to WWVB using PLL techniques, which is broadly similar to how the HP 117A controls its internal 100 kHz VCXO.

FWIW the homebrew active loop antennas discussed in the previous thread are probably not as selective as the HP 10509A active loop antenna used w/ the HP 117A, though Lancaster's antenna probably has more gain. The HP antenna has an internal magnetostrictive filter w/ a bandwidth of 30 Hz (I said 50 Hz in a previous thread which was incorrect), which I believe is a significantly narrower bandwidth than that achieved by the filters in the homebrew antennas. Because the filter characteristic in the HP active loop antenna establishes the overall RF bandwidth of the system, the subsequent bandwidth in the A1 amplifier of the HP 117A is only about 2.5 kHz. Presumably the designers at HP chose this approach to avoid having to

develop a high gain (120 dB) & high Q (Q=2000) RF amplilier, given the state of the art in the early '60s. If you decide to use an antenna other than the HP active loop antenna, bear in mind that the reduced selectivity of the alternate antenna may increase your RFI problem. I would recommend checking the 13CW4 nuvistors in the HP loop antenna with a transconductance tube tester (not an emission type tester) and perhaps performing a frequency response check of the antenna w/ a loosely coupled signal generator before trying alternative antennas.

You might want to try rotating your loop antenna slightly off the desired pointing azimuth, moving the computers radially closer to the antenna null & away from the antenna, or a combination of the above to try to null out or minimize interference from your computers. I'm not sure that relying on your Radio Shack clock would be the best way to judge interference picked up by the HP 117A; a better way would be to hook up a 'scope to monitor the received signal, either to the output of the A1 amplifier or perhaps to the signal level recorder connector on the rear panel of the 117A.

In addition to controlling computer interference, I'd recommend shutting off any dimmer controlled lamps in your house during periods when you're trying to use the HP 117A. Dimmers at my house generate enough broadband interference to render WWVB reception useless, and I'm only ~75 mi. from the WWVB transmitter!

How close is your antenna to the HP 117A? There may be a chance of regeneration if the antenna is too close to the 117A. IIRC HP recommended a minimum 25 ft. spacing, and preferably > 50 ft.

I hope this missive is of some use - good luck.

One simple solution to all of this.... If anyone actually reads this far down the thread.... Just call the phone company, tell them what you want to do, and GET THEIR PERMISSION! Simple, huh? They might want to inspect it or something, but they should agree if it's well built.... Considering that it's for someone with a disability, they will likely be very agreeable.... You may even get to star in their next commercial :-)

>Where is a good place to get single sided board, does it come in stock sheets,
>about how much does it cost?

I get my board stock from a local board house as scrap. The pieces are
irregular in shape, but they're 30 cents a pound. Digikey and Tech America,
and a number of other dealers, sell the stuff in large rectangular sheets, but
not that cheap.

>Also I was just wondering, from the little boards that I got at Radio Shack,
>how do you cut the board? I know I've seen some like cut for a tuna can, or
>for a sardine or >>>SPAM<<< can?

I use a shear. A sheetmetal shear or a paper shear will work. I use a
big hydraulic paper shear that can cut a ream at a stroke (got it from
a print shop that went out of business). That does a nice clean job.
FR4 is nasty to saw, but that may be your only option if you need an
odd shape. Use a tungsten carbide blade, fiberglass eats ordinary
saw blades for lunch. And use a breathing mask, fiberglass dust can
cause pneumonoultramicroscopicvolcanosiliconosis-like symptoms.
(Heh, I never thought I'd find a use for the longest word in the English
language, and hyphenate it to be even longer too.)

>Is the stuff you buy at radio shack ok to use to etch, the PCB Etchant
>Solution? Any hints on it's use, I never could get it to work that well.
>Thanks for any and all help/suggestions/comments

Precise temperature control is essential to consistent results.
I made a bubble etcher from an old aquarium, and it has a tank
heater. But before I had that, I'd put the etching tray in a shallow
pan and run hot tap water into the pan, letting it overflow into the
sink. That kept the etching solution nice and warm at a constant
(more or less) temperature. Every 10 degree temperature
increase doubles the reaction rate of the etchant, so warming it
really speeds things up. Faster etching decreases the amount
of undercutting you get too. But a bubble etcher is the slick way
to go. The constant agitation makes the etching go even faster,
and much more evenly than with the board just lying in a tray.

Two regular diodes in oposite directions will limit the peak voltage to
about
700 millivolts, the same as two zeners would do.

Hello, as promised I'd come through with more complete,
original, good to excellent condition Antique electronic
and audio catalogs.
All are as represented, ALL SALES FINAL on literature.
Prices below are FIRM, and INCLUDE SHIPPING to anywhere
in the lower 48 U.S. states. Others by quote. Some of
these catalogs have stuff YOU ONLY CAN DREAM ABOUT...
Thanks, first come, first served. Much more to come.
Sorry, but this list is in NO PARTICULAR ORDER....
Regards, Joe Pratt

THIS IS WHAT IS HERE RIGHT NOW:

Lafayette Cat.# 740, 1974, 473 pgs. includes order forms,
not mint but real nice, 100% there, 18.00

Lafayette Christmas cat.# 651, 1965, w/order form, 139 pgs.,
very nice,100%, 28.00

Radio Shack "newspaper type" catalog, # 117, Jan/Feb 1962,
"Annual mid-winter sale",near mint except for one small
tear, 40 pgs., 25.00

Lafayette cat.# 670, 1967 100% complete in near mint shape,
511 pages, looks like it did on your coffee table in '67,
yours for 33.00

Key Electronics, Inc. 1963 audio discount cat# A-17, 20
pages, very nice shape and very interesting, 18.00

Radio Shack 1958 "Guide to electronic buying, good shape,
100% complete w/ order form, just CRAMMED with good
stuff, 225 pgs. 35.00

Radio Shack cat.# 96, 1961, 100% complete w/order form,
193 pgs. very nice, 35.00

Allied's 1959 winter supplement #183, 100% there,
56 pgs, very nice 20.00

Allied's March, 1967 winter sale cat# 263, 90 pgs.
100% complete w/ order form, very nice, 20.00

Allied's "festival of values" supplement # 182, 1958
100% complete, good shape 48 pgs, 20.00

Allied's 1960 winter sale book, 105% complete! WITH
original 'Knight kits' glue-on flyer still attached

to front cover, special pull-out Knight kits brochure,
56 pgs, very nice, 28.00

Allied's supplement #133 to 1953 cat.#131, 48 pgs.
of the good stuff, 25.00

Allied's supplement #185 to cat. #180, 1959, 56 pgs.,
"Summer bargains" issue, 100% complete, 25.00

Allied's winter sale cat.#253, 1965, 93 pgs., page
92 a little crumpled in corner, 100% complete
w/ order form, nice, 25.00

Lafayette cat# 660, 1965/66, good cond., spine is
missing a little paper at the top, nice though
100% there w/ order form,511 pgs. 28.00

Lafayette holiday Christmas gift guide # 661,
supplement to the above catalog # 660, 107 pgs.
100% complete, but cover is loose, 1966, 15.00

Lafayette winter cat# 662, 1966 100% there w/ order
form, exc. condition, 107 pgs. 20.00

Lafayette holiday gift guide #671, 1967 107 pgs.
near mint but missing order form, 15.00

Allied cat# 180, 1959, 449 pages of mind-blowing
stuff, 100% complete w/order form, v.good, 35.00

Allied cat# 250B, 1966 505 pgs. of goodies, 100%
complete w/order form, 30.00

Allied radio supllement #132, 16 pgs, 1952,
good shape, 10.00

1960 Federated purchaser cat., 300 pages shows a
little wear, has small hole in the last 6 pages,
but real cool.. lists Genelex KT-66's for 3.50 ea.!!
Try getting that deal these days! 20.00

Radio Shack 1957 cat.# 57, showing some wear but
pretty nice for it's age, less order form, 25.00

Lafayette cat.# 743, 1974, 111 pgs.,100% complete
w/ order form, nice, 20.00

Lafayette cat.#681, 1966, 123 pgs.,100% complete
w/order form, v. nice, 25.00

Lafayette "GIANT Syosset expansion celebration sale
newspaper type cat.# 623, June 1962 64 pgs. very
good cond. and RARE, 25.00

Lafayette cat. # 631 1962 newspaper type catalog,
64 pages, very nice cond, 25.00

Terminal Radio Corp's 1959 high-fidelity audio
digest catalog, straight from "Radio Row"
on Cortlandt street in NYC, 90 pages CRAMMED
full of dreamy items, rare and in nice
shape, 30.00

Thanks to all, I'll post more as I find 'em!

From: "Eric CHAMPION (F5MSL)" <echampion@wanadoo.fr>
Message-ID: <6sbgm5$4i4$1@platane.wanadoo.fr>
Source record: 79724

Hi !

I search for URL where I can get informations on smith diagram. Can you help me ?

A question :
The complex impedance Z = 1+ j1 as a magnitude of about 1.414 and an angle of 45°. When plotted in Smith chart, I found about 62° in the "angle of reflection coefficient in degre" circular scale. Should I read angle there or what is the problem ?

73's. Many thanks for your answer.

Eric / F5MSL.

Over here the best sources is surplus telephone company power supplies. You might also check with building demolition companies, they often have warehouses full of stuff they strip out before knocking buildings down. A third option would be four 12v auto batteries and a big trickle charger.

At the Huntsville Hamfest, someone was selling "Icom adaptors" for
Heil headsets. I have neither, so didn't check it out, but I'd bet it
contains a preamp. You might give RT Systems a call, they may know
about it.

I've used Protel's Easttrax (and some of their other freeware) and it
works
great. This was my first experience using PC layout software and had
no problem learning the use of same from the help file contained
with the software. The circuit I designed using the software was
actually
quite large and it was terrific being able to simple email the files
to have the boards made, etc.

Source record: 79529

I'm pretty clueless when it comes to filter design (never found a simple treatment). I'm starting to play a bit with frequencies below the AM band and wondering if I can simplify my life by filtering out a lot of the monster stations in the area. Doesn't seem likely, but figured I'd ask.

I'm looking for a passband pretty much from near DC to 500 KHz, and I'll trade moderate attenuation at the top of that range for really good attenuation of the area above. Can this be done simply, or are my choices wimpy (~6-12 dB) attenuation above the top, or a zillion-pole filter? Doesn't seem much point to apply 12 dB atten to a 50 KW station 10 miles away, much less to the dozen or so 50 KW stations within 25 miles of here.

I'm more worried about the front end than anywhere else; that's the most likely place to find half a volt overloading the amplifier that's trying to find a couple of microvolts. (My design starts there, because the simplest way to do the rest of the radio is to rip ten parts out of a decent $5 AM radio and have the IF, detector and audio finished.)

Oh, and it would be nice if this doesn't involve $150 worth of Toko coils and exotic semiconductors. :-) (However, all discussion welcome anyway.)

Take another AM radio (preferably a broken one, though a brand new one
will cost you $6.99 at Radio Shack) and use the ferrite coil and tuning
capacitor from that as your output filter AND coupling to the radio.
Comes complete with a calibrated dial to adjust the capacitance. :-)

Hello,

Thanks for responding to our News Group Posting. And once again we are excited to introduce the ever popular "Southern California Repeater Location Guides". This Guide is invaulable to each and every ham that is active on VHF/UHF. So what are you waiting for? Please take a look at the on our NEW Web Site located at:

http://www.rotd.com/worldxn

Visit before the end of next month and take advantage of our specials...

Thanks Again,
Jennifer R.

Source record: 79533

Someone asked about wrinkle paint for a project. Contact a local powder coating company. They can get it in a variety of colors. Reasonably cheap AND VERY PERMANENT!! I screwed up a panel for my own project. 30 seconds to paint - 30 minutes to bake - 13 hours and TWO wires wheels to remove it.

Sadly no - even resistors of 100 ohms or less are frequently spiral-cut.
Scrape the paint off and see for yourself.

As a ball-park estimate of inductance you can use the regular formula
for a solenoid wound from wire. Count the number of turns and measure
the diameter and length of the spiral. It isn't very accurate, but it
will indicate whether the inductance is big enough to cause trouble in
your proposed circuit.

(Wes made some measurements once, and those caused an entirely different
kind of trouble :-)

As I mentioned, the temperature needs to be consistent to produce
consistent results. The exact temperature you choose isn't as important
as using the same temperature every time. That said, I shoot for a working
temperature of about 105 degrees Fahrenheit. That etches fairly quickly
and minimizes undercutting in the bubble etcher. This is for a ferric chloride
solution. I haven't worked much with aluminum persulphate, so I don't have
an opinion on the best temperature for that, though I'd guess that 105 F
would work fine with it too.

One thing to watch is the type of AM radio you are using. It used to be
that they'd use a single transistor as the mixer and oscillator, and
depending on how well designed it was, it might act oddly when coupled to
an external signal. I remember playing with one AM radio, and it was
fine until I started coupling to the loop antenna, at which point there
were all kinds of spurs. This may not apply to recent radios, since they
may use IC's and use a separate transistor in there for the oscillator.

One problem they always talk about when using an AM radio after a
converter is direct pickup of AM signals on the loop. The solution is
to either shield everything really well, or change the loop to a shileded
coil.

Another possibility, though you lose tuning capability, is to bypass the
front end, and use only the 455KHz IF strip.

Though they use more current, a car radio has the advantage of being
fairly insensitive until something's connected to the antenna jack.

Have you checked to make sure that WWV is really receivable when you are
testing? It depends on location, but I've found WWWV at 5MHz is not
as good as at 10MHz. If it's not coming in on another receiver, it may
not be your project that's the problem.

I use an HP432 power meter and the N style bolometer at these frequencies. They are readily available at swap meets for around $100 with a bolometer and cable. There are bolometers available for various waveguide sizes -- they typically go for around $35.00 at the local swap meets. You must use a VOM to test the heads though -- typically only about 10% of the 10 ghz heads wind up being any good.

For radiated power testing, I use a horn or dipole attached to a waveguide transition.

Other alternatives for relative measurement include the HP 5240L Freq Counter with the cooresponding head.

Hi guys,

Thanks for all the info on the 2SC2078. It looks like a ECG235 or
SK3197 should be a direct replacement.

Carl WB6YFZ also mentioned RF Parts stock the 2SC2078. That's
interesting as I was just about to place an order with them for a pair
of 4CX800 tubes, so I'll just add the transistor to the order.

Again, thanks.

I guess I was thinking a little higher temp.BTW, I saw a reference on
the net somewhere
(by a german fellow, I think). He had a concoction of HCL and i believe
30%
peroxide of some type (wasserperoxy**@#_$* or something). Have you
tried anything
other than the traditional stuff? I know that HCL WILL eat up copper. I
had
a jug of fairly strong HCL made as a swimming pool chemical that I used
to
clean and etch concrete. (It sure worked). Pool chemicals are fairly
cheap
since they are used copiously in swimming pools. Dont know about how or
if
it attacks common known etch resists.

Too high a temperature may etch faster than you can control. I'd be
concerned that HCL would attack the resist. Ferric Chloride seems
just about right.

1991. Replacing Ge PNP transistors with Si NPN ones?

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-08-31 00:00:00 UTC
From: "Peter E. Orban" <Peter.Orban@nrc.ca>
Message-ID: <35EAFD3C.41C6@nrc.ca>
Source record: 79551
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.shortwave

I have an old shortwave radio (VEF 204) that uses Ge PNP transistors.
In case of repair, I am curious about replacing all of the germanium
transistors with Si NPN ones. Beyond turning around the battery, the
polarized capacitors, and changing the bias for the higher Vbe, what
else should I think of?
Any comments, on noise, sensitivity, AGC effectiveness, unwanted
osillations, and other advantages/disadvantages?

Thanks, Peter, VE3PEY

Hi there...

A relay will not be fast enough. The ring is 96 volts at 25 Hz and I have seen it damage audio equipment hooked up to the tele line.

For a cheap solution, buy a low cost phone, open it up, and tap off where the handset speaker goes. You may need a small audio isolation transformer between the computer and the handset output of the phone. To not take a chance, go to any of the electronic parts stores and enquire about a small audio transformer 600 ohms to 600 ohms (for example) anything from about 300 ohms up to 2000 ohms will work okay. I did something like that, and I found a transformer that was 900 ohms to 1200 ohms with a centre tap. I put the 900 ohms as the primary and used the centre tap of the 1200 ohms as the secondary. This worked.

A number of years ago I used to see these type of minature transformes at Radio Shack. They are sometimes popular for small home audio projects.

Lots of luck...

The HP434A calorimetric wattmeter can be bought for about $100. It's
definitely in the boat anchor class and no longer made.
Frequency range is 0-18 GHz (from memory, mine's at another QTH).
Power for FSD of meter varies from 10 mW to 10W so it's less sensitive
than the bolomoter types but doesn't need a directional coupler for
some measurements that would require one using a bolometer unit.
It is self calibrating because of its DC response, a current generator
to give , I think, a watt into its 50 ohm load is included. Input is
through an N connector.

And, the detector diode.... Have you considered PNP
silicon replacements? Make sure the IF transistor replacements
match the AGC system the radio uses.

Source record: 79555

Maybe I did not post as elloquently as I should have but where did I say that film and carbon resisrors are soppiral in their construction? There must be something in my original post that I missed? Wirewound resistors usually 5 watt rating and greater are spiral wound and that I did put in my post.

The construction of film resistors is done by screening resistive material onto a substrate, baking it and then lazer trim to the value needed. The substrate can be round or rectangular. Lazer trimming increases the base resistance per square to the desired value. There maybe a small inductance of the path that the current takes but the inductance value is in the pH range. They are not a problem until you get well into the GHz range.

Anyone have any idea how over-the-air cloning of the DJ-G5T works? Such as how the data is encoded into audio, what bit rate, etc.

A possibly related question is whether there might be an undocumented control pathway for the DJ-G5T? I had plugged a patch cord from the DJ-G5T into a portable cassette for the purposes of recording satellite passes (apparently common practice amongst some AMSAT folks using hand-held antennas), but did not have it fully plugged it. It seemed to switch bands, change channels, and make beeping noises indicative of illegal commands when the partially plugged in patch cord was wiggled. Might there be something like a serial control mechanism which isn't documented (such as for the Yaesu FT-5100, which i can control from my laptop)?

2002. Quality Panel Meters on Ebay (Hermetically sealed, glass lenses)

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-08-31 00:00:00 UTC
From: Radio Randy <rjones@plix.com>
Message-ID: <35EB771A.6DB7@plix.com>
Source record: 79562
Cross-posted to: misc.industry.electronics.marketplace,rec.radio.amateur.homebrew,rec.radio.swap,rec.antiques.radio+phono,rec.radio.amateur.boatanchors

Hi Gang,

My selection of round panel meters (ranges 0-50 vdc to 0-500 vdc and 0-50 adc) are still available on Ebay. These meters were built around 1958 and were removed from an Air Force computer system (using tubes!).

The ammeter has a 50 mv full scale sensitivity (could be used for a 0-50 millivoltmeter) but comes without the "external" shunt.

You really SHOULD take a look, prices currently range from $1 to $6.50. Follow this link:

http://cgi.ebay.com/aw-cgi/eBayISAPI.dll?ViewListedItems&userid=radio_randy

Thanks.

Radio Randy

>spacing.

No, no. This isn't related in any way to CB, or to interferre anything.
I choose this freq becouse I can get cheap crystals to try before order
aged ones that can be used in a ovenized source for a multiplier:
27*16=432, 24*18=432, 27*48=1296, 24*96=2304 and so on.

I intend to make this to gain experience with wideband modulation in
the bench, to transmit high speed data over packet radio in our higher
UHF/SHF bands.

The requeriments for the phase shift modulator are a moderate bandwidth
of about max 500Khz and 20Khz min of the modulating signal.

So I like to find some phase modulator that I could simulate and
understand before plug the soldering iron and start to try.

I've found a phase modulator module "PMP-3R Series ANALOG PHASE MODULATOR"
from Merrimac but I don't know how to model it to simulate in spice and
how homebrew it to experiment, since I probably could't buy one enought cheap.

>You may have to get a 10 meter rig that can be opend up to operate down
>to 26.000 MHz so that you can tune the transverter all the way down to
>144.0
>
Just got my news reader working, so this reply is several days late.

Just change the crystal in the transverter and you can use your HF rig from 28.0 to 28.1 to cover 144.0 to 144.1. You will need a crystal that comes out at 116 MHz after the multiplier. (28+116=144 144-116=28)

Down East Microwave also kits. Not only for 2, but for all of the bands from 50 MHz on up. Check out their web sight. They have a nice on-line catalog.

Actually, I think it won't. I don't have my chem book handy, but I seem
to remember that nitric acid (HNO3) reacts vigorously with copper, but
HCl doesn't.

> I had a jug of fairly strong HCL made as a swimming pool chemical that I used
> to clean and etch concrete. (It sure worked).

HCl does indeed react with concrete, especially fresh concrete (fizzes
nicely). But that's because concrete is alkaline (basic). These kinds
of reactions can be very compound-specific, and reacting with concrete
doesn't mean it'll do anything with copper.

BTW, I used to maintain a medium-sized pool, and I would never consider
using hydrochloric acid *in* the pool. Hypochlorites work well enough
and are much safer.

> Pool chemicals are fairly cheap
> since they are used copiously in swimming pools. Dont know about how or
> if
> it attacks common known etch resists.
> Don

I recommend staying with FeCl3. It's not all that expensive, it's
pretty readily available (you can crystals or solutions), and it's
reasonably safe.

dx 390 radio shack sw reciever with
box manual ect....almost new works well and no blemishes

$75 +shipping

<2>
mfj 451keyboard keyer with keyboard,
wall adapter, manual, box, keyinput

sells for 99 in the mfj catalog, street retail?

$50 + shipping

<3>
mfj 564 iambic key paddle wired with
a stereo jack to be used with any iambic
keyer to get dits on one paddle and dahs
on the other

$30 +shipping

<4>SOLD
IC 22S

<5> SOLD
radio shack digital power meter.

<6> tentativly sold
astatic D104

<7>
d104m6 mobile amplified mike
7 volt battery cage broken, you can
get another from astatic for $2.00
no connetor for radio

$25 shipped

<8>
I also have about 2 dozen 4 wire
mike cords. These are the heavy duty
belden cables that I bought surplus cheap!
I will pass the cheap on to you

these normally go for 9.95 each

$3.00 per cable shipped

<9> sold

<10>
matched pair of mrf497's I was going to build a radio
with high output but the idea fizzled...***note these are the
high output transistors that are used in the hr2510/hr2600/htx100
high output mods****
I also have a matched pair of mrf492's that I was going
to build into a 6m amp, but am going the route of a
larger output radio.

497mp $50
492mp $50

<11> Radio Shack scanners,
pro 2035 1000 channel scanner with excellant recieve
25-512/760-1300mhz
pro 2045 200 channel scanner 29-54/108-174/216-512/806-1000mhz

make offer on either one

or I will take partial trades
I am NOT opposed to trading up or down
or buying outright

looking for....

KAM version 7 or later with software/cables

6 meter radio will consider allmode

2kw or better tuner with wire/and dual coax outputs
with meters. MFJ/DENTRON/??? lets talk

ham IV or bigger rotator

I can be dealt with, if you have trades, let me know

Hi !

I get some answer and I fix the problem about converting x+iy into
<<REFLECTION COEF polar form>> and NOT simply into its <<polar form>>...

But I always search for interresting informations (and software) on Smith
diagram on the web.

73's. Eric / F5MSL.

As a rule of thumb, 20 AWG is about 20 nH per inch.

Metal film and some carbon film resistors are not "wound" in a helix,
but the higher values are made of lower resistivity material and are
trimmed to higher values by a spiral groove cut into the body.

Source record: 79673

Ok, I'm out of luck and ideas.

Building a 5Mhz WWV reciever by building a simple converter with an IF on 1300Khz for use with an AM radio. Could someone help me with a coil/cap combo for the front end and then a filter for the 1300KHz output. I've read the handbook, tried and tried again but can't seem to get it to work.

Im using an NE602 with a 3.686 xtal, I figured 5Mhz in minus 3.686 = 1314KHz, is this right? Based on some casual spins though several shortwave bands it appears to be mixing, just not where I want it to.

Eric,

Go to: http://mot-sps.com/rf/designtds/mimp.html

and download the file mimpzip.exe

This is a free impedance matching program that includes Smith
charting.

Also, I have a program from W9DMK that does impedance matching and
Smith chart plotting. I'm not sure where I found it, but a search
will probably turn it up.

>interest? I never even thought of a resistor having inductance (or
>capacitance) until I read your post.

Resistors have both inductance and capacitance, just as capacitors have inductance and resistance and inductors have capacitance and resistance. In other words, there aren't any perfect components.

Many circuit designers assume "perfect" components and are puzzled when their circuits misbehave.

>

Hmmm. Does this mean that you believe that circuits are always designed with 20% tolerances (they aren't) or that a receipe that calls for five eggs fails when only four are used?
>
>But to answer your question, check out the MIL specs to which the
>resistor is built. Somewhere in fine print you will find the reactance!

No, you won't. First, reactance is frequency dependent, so it would be the inductance that would be specified, except that it isn't either. To view some (but not all) MIL specs try:

Cheap amplifiers??? Alltronics sells 3 kits $6 (?w), $7(1/2w) and $14(1w), Tech-America sells 2 kits 2.5w and 4w for about $14. Any local electronics store probably sells kits. With a good 'junque' box, you could build some without spending anything. Or maybe you should consider a multiposition switch? Good luck on your project.

Whatever means is used to specify limits on reactances of resistors....
the mil specs may not be very usefull. I assume they define a limit or
ranges etc that are required, and may not be indicative of what is
available, particularly if they are old.

Peter,

I built the Smart Battery Charger kit offered by A&A Engineering in
Anaheim, CA. I have used it for years and been very happy with it. It
is the unit which was published in the June 1987 QST.

You can contact them at (714) 952-2114

It would seem a lot easier just to locate some replacement germainium devices. They are still around. If you have to go to silicon, pnp devices would be somewhat less work, but I doubt the germanium biasing schemes would work out - the Vbe for germanium is .2V and .6V for Si. Granted, the germanium RF devices such as used in FM radios are scarce, but the rest should still be available.

Painting antenna parts that are subject to corrosion is a good idea. Many high-quality commercial antennas are painted. If you live in an area where salt spray corrosion is a possibility (like Florida or an island like the Phillipines!), then paint will certainly help prolong the life af any non-stainless steel hardware.

If you are spraying over insulators, be sure the paint is a good insulator - without metallic content. Otherwise, the paint should not affect the antenna performance.

My next step was going to be to play with detectors. I'm playing with an idea that would let the detector PLL(s) do the input frequency selection. A parallel-tuned circuit would be a nice filter on the front end, but when I get to the next stage the requirement for manual tuning defeats the purpose. And I simply can't conceive of trying to get a stable range of 5-500 pF out of varactors; is that even possible?

I also played with the idea of preamplifying the signal before it hits the noisy resistor (i.e. the parallel-tuned circuit at resonance). But field strengths from local broadcast are high and really complicate the idea of designing a small-signal amplifier; I'm sure any decent antenna will give me a volt from each of two or three local stations, so just for a 1 uV signal we're talking over 120 dB of dynamic range. So the preamp is out (with me designing it, anyway) unless I can get some serious reduction of those BCB signals.

So basically, a lot of ideas came from the thought "what if I could".

It seems unlikely to me that an unlicensed operator would go this route to break the rules. A few mW on 50MHz FM isn't going to net a lot of contacts, is it? Now, if the question was about 10-meter radio mods, or amp mods, then that would certainly be 'suspicious.' Many hams choose not to include their calls on the net for personal security reasons, i.e. the availablity of our home addresses, where all our precious gear is located.

To answer the question: unlicensed operation is *not* a criminal offense, but rather civil. Unlicensed operation on 6M would subject the violator to the usual FCC civil sanctions, confiscation of gear, a fine, etc. I dont mean to discount the seriousness of illegal operation, but the distinction is an important one.

The MRF476 is the Motorola replacement although it seems
pretty light especially for FM service. The same goes
for the NTE/ECG235. The MRF475 or the NTE/ECG236 would
be my choice. The downside to either of those is that the
output will be lower unless you're willing to re-resonate
the output circuit.

He wants to go the other way, so he'd need to tap into the microphone
circuit. Same idea though, you should be able to connect in the
transformer either in series with the mic element, or in parallel (with
a capacitor in series with the transformer). I think most phones use a
electret mic with a built in FET, but the same idea would work with a
carbon mic, too.

Another thought. This is the same sort of circuit as a "Music on Hold"
adapter where you can connect a radio or other source to the phone so
it plays when you're holding someone.

> assemble the supporting circutry. Thanks & 73's
> Seth van Ommen

I have a couple of solid state boards that are clean pulls from medical equipment. They have been tested at 450w key-down cw output. I have spare finals for each. In the medical application they always run amps way below capacity (in this case probably 200w momentary) because they need a pure signal and reliability, so these have not been stressed in use. You'd want to increase the wattage of a couple of resistors, rewind the rf transformer to be broadbanded (the boards are designed for 13.86 MHz), and increase the size of the heatsink. These devices require 48v.

The swr protection circuitry, switching, output filtering, etc. scared me off from this as a first homebrew project! I'd like to recoup my cost, $110. per board shipped conus. $40. shipped for each pair of replacement devices. Both boards and the four spare finals $300.
shipped conus ... OBO. Trades are a consideration ... especially a 8877 tube.

Hello All, I was just wondering if there is an online source, (or maybe it's really simple) to allow me to know which transistors I can sub for others in projects.

Like if my project calls for 2n2222, but I have 50 other kind of cheap NPN's around, which ones can I use...

Not just for the 2n2222, but for transistors from old projects that I see, and just whatever...

Thanks for any help..

I am considering buying an Icom IC-706 or 706mkII. Since my favorite mode is CW I would like to hear comments from anyone on how well this rig performs on cw. How is Icom's optional CW filters in this rig? Good S/N ratio ? I need something more portable to drag back and forth from my cabin and since I am currently lugging seperate rigs for HF, 6 and 2 meters the 706 would better fit my bill. Any comments at all would be welcome please.

Tim-

I cannot give you a fair reveiew on CW, as I do very little CW work. The IC-706 is an excellent rig though for all-around work. The MKII model has anumber of enhancements over the original model, and the current incentives from Icom make it almost a no-brainer as to which model to choose.

Portable, the 706 is very compact, rugged and a good performer on SSB and FM. The menu system does take some getting used to, but it grows on you. I have used mine now for several years, and have just bough tthe matching AT-180 for it. The separation kit is almost a must for mobile use if you are going to actually mount it. I use a Timewave DSP-9+ on SSB and don't miss the filters at all.

I would choose the IC-706 over and over again, but I have to admit I would have waited for the MkII if I had known it was coming.

Go buy one. You'll be hard pressed to find so many features in a small box like this.

It's ok. I have used one at a field day that had a cw filter. It was pretty tight. But I wasn't overly impressed with the overall audio quality of the rig. Seems to maybe have a tad to much rf gain on the low bands. But I imagine this is due to catering to the mobile ops. It wasn't distorted or anything just kinda flat sounding. But heck, what can you expect from such a small radio, and also I'm spoiled on my 830 and other rigs. Good sensitivity on the high bands. Overall I'd say it's ok. Reliable with a decent track record. And small. I use a old IC 730 in my car, and has been a very reliable radio over the years. MK

Peter: You can probably just put it across a regulated 13.8 volt
power supply. I put an ammeter in series to make sure that the
charging current does not exceed about 1.5 amps. Keep charging until
current drops to around 70 milliamps. 73 Bill N2CQR

2057. Bow-Tie / Patch / Crossed-dipole antenna

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-02 00:00:00 UTC
From: cmoss@freenet.uk.com
Message-ID: <35f91b24.3219123@news.freenet.uk.com>
Source record: 79606

Hi.

Is there anyone out there who can supply details on a Bow-Tie or Patch antenna for the 24cms band with a 50R unbalanced feed input (coax).

I need to build a simple fairly flat antenna but with a very broad beam width and not a lot of gain, preferably cross-polarized or circular as the source of the transmission is continuously changing it's polarization (vertical polarized for most of the time though).

I guess a crossed dipole with a crossed-reflector would be idea but i no longer have the details of the different polar patterns for different reflector-dipole distances - i've lost my VHF-UHF manual in a house move.

Maybe a short helical beam ?

Thanks to all who supply help with this query of mine.

Clive.

2058. Transverting 10 m rig to 2 m.

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-02 00:00:00 UTC
From: wk@antispamfrc.niwa.cri.nz
Message-ID: <35ed106d.26033186@131.203.59.8>
Source record: 79607

Thanks for reading this message. I have an old, but perfectly good Ten Tec 'Triton' 540 transceiver, no longer in use as primary HF rig, which I am wanting to use in the 2 metre band, both for SSB/CW DX-ing and for the linear transponder satellites (2 m uplink).

A quick search of the ARRL and Radio Communications Handbooks ideas on 10->2 transverters was fruitless. No cookbook receipes were found.

Whilst it may appear to be a simple enough exercise to knock out a quick crystal train to 116 MHz, followed by a diode ring mixer and linear amplification/band pass filtering on 144-146 MHz, it seems to me there is a little more to it than just that.

My main concern with this scheme is trying to keep the 5th harmonic of the exciter out of the output passband. It will show up as a 5th order product and will be almost impossible to get rid of when tuned to 145 MHz (29 MHz).

My question is this: what is the recommended transmit conversion scheme? My pick is, that it would have to be a dual transmit conversion to get around the 5th order problem. Is there a smart way to achieve the double conversion with a single oscillator?

Any suggestions appreciated. Yours in homebrewing,

Wilbert, ZL2BSJ

It's OK. I have worked a few of them. Thought it sounds kinda of mushy above 35 wpm when in QSK mode. Like it's chopping some of the dashes or something. Don't know how well it RX's. Can only tell you what it sounds like over the air since I don't have one.

I can say, the faster you send, the better your signal must sound due to static and QRM. It's takes too much effort to guess what your trying to say... Best CW still comes from older rigs with a manual PTCW switch.

I would add a hefty diode to make sure the battery never discharges into the powersupply in case of power failure. Any old high-current diode will do, an old "top hat" type from your junkbox or a 1N400x something.

And a high-wattage low-resistance resistor, just to limit the current in case the power supply voltage can't be adjusted to give you the suggested current (less than 1.5 amps). Maybe 5 ohms at ten or twenty watts. This will also limit the initial "inrush" current when you turn the power supply on.

Just put these in series with the pwr supply, current meter, and battery.

The nice thing about this hobby is that you can *experiment*. The trick is not what can you substitute for the 2N2222, but what will work in the project. 2N2222's are cheap, have good gain, handle a moderate amount of power and are useful into the VHF region, but you don't always need all those at once. Select a transistor to fit the application or plug one in to see if it works. Of course, in either instance, try to make sure that the important characteristics are matched or you might let all the smoke out and it won't work.

I'm not sure about the actual versions; I only used an old one once:
File export functions were restricted, so you couldn't use Gerber. I
don't know about the libraries in the "full" version, but the trial
version seems to contain only most common parts.
And: The file size is limited to 16 or 32k, no matter what kind of
file (pcb, bom,...)
This is what I remember (or at least hope to), so it might be wrong or
not up-to-date any more...

Hello, I have the following literature that is out of print,
and very hard to find. These are very high resolution LASER
monochromatic reprints of the rare originals. All are professionally
done with original style binding. All sales final on literature,
and I'm sure you'll be pleased. All prices INCLUDE POSTAGE, in the
continental USA. Others by actual quote.
Thanks, and if you need tubes, visit our sister screename,
Tubecntral@aol.com

TRANSFORMER BULLETINS/CATALOGS/MANUALS:

KENYON "Quality transformers",23 pages,has some writing in numbers
on the front cover by the original owner,but a real information
getter. Covers ALL transformers available in Dec.1st,1941.
Even has the "blown in" price update sheet! Price $9.00.

PEERLESS Transformers, Catalog 1948 - 1,original owners name
on upper right hand corner, nice info, not perfect but nice,
Price $8.00.

SNC Transformers, January 1, 1947,13 pages plus original owners name
spelt on upper right hand corner,beautiful copy, has "blown in"supplimentary
catalog page,price sheet, and August price update sheet! Price $8.00

STANCOR Essex #2,069,42 pages, a REAL NICE MANUAL/CATALOG,has EVERY thing!
A real good info source,Price $10.00

STANCOR Essex Catalog # 140 H, 21 pages plus Numerical index and
October 1, 1948 price update list, very nice, $9.00

THORDARSON "Transformers by Thordarson, No. 400-FX 1942, A beautiful
source of info, 27 pages, Price $9.00

THORDARSON 1941"Tru-Fidelity by Thordarson, an UNBELIEVABLE catalog, real
nice pictures of early Broadcast transmitters and an excellent source
of audio info, 19 pages,real nice. Price $10.00

UTC Transformers, reactors, filters, Catalog# 500,looks like early 40's
another real nice, illustrated Catalog/manual, 22 pages, Price $9.00

UTC transformer components, Spiral-bound Excellent catalog/manual,
really in depth, Bulletin# PS-405,)ct. 15, 1941, includes "blown in"
price update for Dec. 6, 1946.Another excellently illustrated info
source, 34 pages, Price 11.00

EITEL-McCullough's "THE CARE AND FEEDING OF POWER TETRODES", 1951
25 pages crammed full of information IN DEPTH! Has everything you
ever wanted or needed to know about running these tubes, a real

nicely illustrated easy to understand manual, Price 10.00
Thanks for reading, if you have any questions or need to order,

A ramp modulator would do what you want.
The basic circuit works like this:
The RF input (27 MHz) is changed to a ramp waveform. This ramp, and the modulating source, are fed to a comparitor. The output is differentiated and sent to a one shot, which results in a constant duty cycle output pulse which is phase modulated by the input source. The modulation is very linear, much more so than could be obtained from a variable reactance modulator. This type of circuit has been used in several commercial FM transmitters with good results.

Don't know, but I'm sure there are ICs available which will do this with a few external components.

Good luck..........Cliff

> Jay KA9OKT

Yes, the 103s are .01 uF, and the 104s are .1 uF.

The 1 and the 0 are significant digits and the third
digit (in this case a 3 or 4) is the multiplier.

For example, a 103 equals 10,000 pF. It's a 1, a zero,
and three more zeros with a pF on the end. Move the
decimal six places to the left to convert pF (picofarad)
into uF (microfarad).

Well I've got an Icom IC-706MKII in my '86 Chevy S-10 pickup.
It's mounted in the space below the AMFM/cassette player.
Don't run mobile CW with it as I only use it for SSB & sometimes FM.

It also makes a great SWL reciever

Antenna is a Bugcatcher. Don't use any kind of antenna tuner.

I would suggest that you pick up the book "Microwave Transistor Amplifier" By Gonzalez. This is the book that will explain all linear S-paramter calculations to you. There is a 2nd Edition out that I haven't looked at. THe first Edition is a great reference. Beware, this isn't real easy math.

Hello, I hope I am posting this to the right ng.

I have a Uniden SMU300K UHF 20 channel radio that had a transistor go out in it. The location is silk-screened as Q412. The part number was unidentifiable. I called Uniden and the parts rep told me that the SMU300K does not have a Q412. I beg to differ. Its there, right in front of me.

This transistor controlls the on/off and volume functions of the radio. Shorting the right two leads will power up the radio, but will be full volume.

If anyone can help me identify this part I would greatly appreciate it. I would like to have this radio re-programmed for GMRS or amateur use.

Speaking of programming, how difficult is it to get it re-programmed?

Running 140 watts out from a HW8.....
Well first you must be sure that the amount of spurs from your radio
will *NOT* cause any problems! Running 1-2 watt, most spurious and
harmonic signals does not cause any probblem but then amplifying these
20 dB will make a big difference!!!

One thing that usually cause big trouble is when people hook up their
VHF handie-talkie with a 100+ watt amp. The spectral purity from such
a radio is adequate for this amout of power and can make your close by
HAM friends pretty upset, and of course FCC...

Cheers

[...]

Thanks for the reference, Dave. I'll try to get the book. But I was looking for web resources to speed things up.

I have downloaded everything I can find, including the HP appnote mentioned above. The math really doesn't seem that bad, and I'm looking for code examples to show how the method works.

I did find an example in Pascal for the basic Smith chart. It's on

http://sss-mag.com/smith.html

and is in the file

http://sss-mag.com/zip/smith1.zip

So, that's part of the problem solved. Now for S-Parameters!

Best Regards,

Mike

Don't spray paint on any compression connections or rf connections. The
paint is thin enough to wick or work its way into compression connections
(such as telescoped aluminum tubing connected together with hose clamps)
and into RF connectors.

Hi Jay;

Here is the color code.
Lets us the following 103M

1 = the first digit
0= the second digit
3= the multiplier (1000 in this instance)
M=the tolerance (+ or - 20 percent in this instance)

This capaciotr is a .01uf capacitor.

104M would be a .001uf.

This code give you the value in pf incase you were wondering how they translated into the value I gave you.

These charts are in the ARRL handbooks.

2094. Converting 50Hz to 60Hz for transformer???

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-03 00:00:00 UTC
From: stickler@infospring.com
Message-ID: <6smarp$plj@sirius.infospring.com>
Source record: 79496
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.misc

Hey folks,

I live in Finland, where the power is 240VDC at 50Hz and I have a really nice American 1500W step down transformer, 240->120VAC. Unfortunately, it was designed to be used in the US at 60Hz, as a house transformer, and it gets too hot at 50Hz (I figure the wires are not a large enough gauge, or the core is not optimal, for use at the lower frequency).

How difficult would it be to build a device which converted 50Hz 240VAC to 60Hz 240VAC, for frequency matched input to the step down transformer?

Such large transformers are very expensive here and I'd love to be able to put the one I have to good use cheaply and safely...

Cheers,

Patrick

If you are going to go the trouble of converting 50 Hz to 60 Hz why not just convert from 240 v to 120 v (which is what the transformer does anyway). I think that the circuit would be quite complex and that you would loose a lot of efficiency in the conversion. Let me think. You could convert 240Vac directly to DC if you wanted. Then run it into a Dc to AC inverter, which would require a 60 Hz transformer anyway (which I suppose could be the one you have). [No, I do not have a schematic.]

Does your transformer get hot with no load? If so, it is probably the core. If not, just derate it, perhaps to 1000W (or what ever).

I have read about this problem, but never actually seen it. I guess you can go one direction (50 Hz transformers on 60 Hz) but not the other, as you have discovered.

Indeed you can and most usually, it's a core flux density problem Basically, at 50 Hz, there's 20 percent not enough core there. The only way to use it would be to rewind it with smaller wire, more turns and get the flux down below saturation. (You shoulda been around to see the old 25 Hz transformers. There still are some up in Canada.)

I assume that you mean it gets hot with no load. The problem is that the primary reactance is too low for use at 50 Hz. If you could increase the primary turns by about 12%, it ought to run cool. But you'd need to increase the secondary turns too in order to still get the same voltage. There probably isn't room on the core to do that.

>How difficult would it be to build a device which converted 50Hz
>240VAC to 60Hz 240VAC, for frequency matched input to the step down
>transformer?

Well, you don't have to convert it to 60 Hz exactly. Anything 60 Hz or greater will do. So all you need is a chopper circuit in the primary which operates at any convenient rate. A pair of SCRs driven by a free running multivibrator (555 chip) would suffice, but would generate some nasty hash. Lots of shielding and bypassing are required. That's easier at higher frequencies, so chop at a 1 kHz or higher rate. Then the lowpass filter you need on the output of the transformer won't need to have such a sharp cutoff to get rid of the switching hash.

Of course if your *loads* need 60 Hz (motors, clocks, etc) then this won't work. You'll need sinewave 60 Hz in that case, and that's much more work than the transformer is probably worth.

>Such large transformers are very expensive here and I'd love to
>be able to put the one I have to good use cheaply and safely...

It may be worth your while to consider rewinding it, even if you have to use smaller wire, and thus have to derate it a bit.

Hello, I am looking to make a radio transmitter that is somewhere between 3 and 18 watts. I will need very good directions because I am a beginner, including parts list, schematic, and just how to make it in general. Webpage addresses or book titles would be appreciated. Also a quick question. Is an oscillator and an amplifier hooked together just a transmitter?

Thank you,
Jonathan

: >really nice American 1500W step down transformer, 240->120VAC.
: >Unfortunately, it was designed to be used in the US at 60Hz, as a
: >house transformer, and it gets too hot at 50Hz (I figure the wires are
: >not a large enough gauge, or the core is not optimal, for use at the
: >lower frequency).

: I assume that you mean it gets hot with no load. The problem is that
: the primary reactance is too low for use at 50 Hz. If you could increase
: the primary turns by about 12%, it ought to run cool. But you'd need to
: increase the secondary turns too in order to still get the same voltage.
: There probably isn't room on the core to do that.

: >How difficult would it be to build a device which converted 50Hz
: >240VAC to 60Hz 240VAC, for frequency matched input to the step down
: >transformer?

: Well, you don't have to convert it to 60 Hz exactly. Anything 60 Hz or
: greater will do. So all you need is a chopper circuit in the primary which
: operates at any convenient rate. A pair of SCRs driven by a free running
: multivibrator (555 chip) would suffice, but would generate some nasty
: hash. Lots of shielding and bypassing are required. That's easier at higher
: frequencies, so chop at a 1 kHz or higher rate. Then the lowpass filter you
: need on the output of the transformer won't need to have such a sharp cutoff
: to get rid of the switching hash.

Of course at 1kHz, you might be getting into the area of too high a freq
for the core. Also...commutating SCRs can get tricky; IGBTs these days
probaby would make a lot more sense. 240 volts at 1500 watts is only
about 6 amps, which should be very easy for IGBTs... but read on...

: Of course if your *loads* need 60 Hz (motors, clocks, etc) then this won't
: work. You'll need sinewave 60 Hz in that case, and that's much more work
: than the transformer is probably worth.

: >Such large transformers are very expensive here and I'd love to
: >be able to put the one I have to good use cheaply and safely...

: It may be worth your while to consider rewinding it, even if you
: have to use smaller wire, and thus have to derate it a bit.

An alternative is to supplement it with a small transformer or two.
If you can come up with a 50Hz transformer with a 30V 6A and a 15V
12A secondary, and 240V primary, you can hook the primary to

your line, then connect the 30V secondary in series with the primary side and the 15V secondary in series with the secondary side of your big transformer, all properly phased, so you get 240V-30V = 210V into the big guy, and 105V out of the big guy, plus the 15V from the little guy, for 120V output. If you don't need isolation between primary and secondary, only stepdown, there may well be another way you can hook things up to have them work well, perhaps not even requiring a second transformer if the one you have has a split primary.

It was brought to my attention I forgot to include some information. I wish
to broadcast over the FM radio band. I wish the transmitter to send out a
fairly clean signal.

>
>Mike
>

If Pascal is ok with you, you could order the program Puff from Caltech ($10) along with the optional source code diskettes ($10). See:

http://www.systems.caltech.edu/EE/Faculty/rutledge/puffform.html

This should have what you want but there's a lot there so might take a while to sort out.

Back about '92, RF Design magazine offered some software diskettes. I looked at their site (www.rfdesign.com) and don't see them now. If you can find them, RFD-0392 might have some of what you are looking fo too. Some C and some Basic.

I have a book from Howard Sams, "Electronic Prototype Construction" by Stephen D. Kasten (c) 1983. It describes etching using Cupric Chloride as an etchant. Formula: CuCl2 - 200g, Concentrated HCl (35%) - 100g, Water to make 1000ml. The advantage is that after etching you add more HCl then bubble air through it. There is a reaction with O2 and more HCl which converts the disolved Cu to more CuCl2. You should never need to throw it away. In fact your solution grows.

Haven't tried it myself. He says that at 120-130 deg F it etches a board in less than 1 minute. There is some hazard with the HCl.

Just offering another option. There is a long description in the book of how to keep the solution maintained. Requires a hydrometer and is not too simple.

This sounds too good to be true ! The echant regenerates itself... and
etches a board in 1 minute. Does the book give any sources to get the
cupric chloride (i guess thats what it would be called)? If you have
time, it would be nice to know a little about the management of the
reagent.
Thanks,
Don

To answer simply, no and no. Null modems are used to directly connect two computers by cable. It consists of a cable or adapter that has, at least, the transmit and receive data lines swapped on one end so that the computers will be able to send and receive data correctly. A standard modem is needed to connect a computer to the phone line. I don't know that you actually want to do, but if you want to connect two nearby computers together without running cables between them, try getting wireless modems.

sounds like an SCR. which is a little like a transistor but switches current
when the forward voltage gets high enough the scr conducts and heavy current
flows through the circuit. In other words it is a gated device.

A transformer designed for 50 HZ will work just fine at 60 HZ. The reverse
is not true.

As far as generating 110 VAC or any voltage for that matter, the typical
way is with an MG set, aka a motor-generator set. In fact, this is the
easiest way to get such niceties as 440 V 3 phase power from 220 V single
phase -- horribly inefficient, but it works. You can also go from 220VAC/50
HZ to 110VAC/60HZ.

The Findlay Radio Club will hold its 56th annual HamFest
and Computer Show on Sunday, September 13, 1998 at
the Hancock County Fairgrounds in Findlay, Ohio.
This is the best and biggest Fall season 'fest that we know
of in the Northwest Ohio area. We hope you can make it.

Check http://www.bright.net/~kanga/w8ft/hamfest.html for
details, or if you don't have web access contact hamfest
chairman Dave Hoxworth at 419-423-5792, or as a last
resort you may contact me.

Hi.

Does anyone out there know where i can find a data sheet on the BLU98 GHz's npn transistor at all ? ... i need to calculate input & output matching component values to work at 1.24GHz

I could do it by trial & error but the PCB inductors are PCB tracks (striplines) so a rough guide would be helpful.

Also anyone know what an MC1376P motorola chip is (any data sheet for it) ?

Thanks to anyone with any help !

Clive

2123. 24LQ6 v/s 6LQ6

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-04 00:00:00 UTC
From: Richard Hernandez <sfzgznuc@scfn.thpl.lib.fl.us>
Message-ID: <Pine.SUN.3.95.980904110452.25061A-100000@scfn>
Source record: 79435

I have an old 10m thru 40m amateur amplifier which has seen better days. I would kinda like to refurbish it, however, it is based on 6LQ6 sweep tubes (four 6JG6 tubes driving four 6LQ6 tubes to be exact). What I was wondering is, can 6LQ6's be replaced with 24LQ6's with simply the addition of a 24volt filiment transformer? Are these tubes similar except for the filiment voltage (they definatey are much cheaper)? I really know next to nothing about these tubes so any help would be greatly appreciated. Also, might there be a cheap alternative to the 6JG6 or 6JT6?

Thanks,

Richard H.

2124. WTB:Stereo MPX units and 19 and 38 KC transformers (Miller,etc)

: >probaby would make a lot more sense. 240 volts at 1500 watts is only
: >about 6 amps, which should be very easy for IGBTs... but read on...

: Can you elaborate on the IGBT's (I'm quite out of my depth here...).
: Perhaps a circuit diagram is available somewhere...?

IGBT's are "insulated gate bipolar transistors," kind of a cross between
a power MOSFET and a bipolar power transistor. They are fairly
inexpensive, and can handle a lot of power, especially in the few-
hundred-volt range.

The basic idea: bridge-rectify and filter your line voltage directly
from the line into big capacitors. That gives you something like
340 volts DC. Then use an "H-bridge" arrangement to drive the
transformer primary. The H-bridge consists of a switch (i.e., IGBT)
from each end of the transformer primary to each side of the power
supply DC voltage. So the four switches are connected like this:

switch connects between
A trans. 1 and +340V
B trans. 1 and common (- side of 340V)
C trans. 2 and +340V
D trans. 2 and common (- side of 340V)

Then, cycling at 60 times a second, you turn on switches A and D
for some milliseconds, turn off switches A and D for a short time,
turn on switches B and C for some milliseconds, turn off switches
B and C. The "on" time for A,D is the same as the "on" time for
B,C. And the two "everybody off" times are also equal. You can
adjust the total "on" time percentage so that the output waveform
has the same RMS value as a sinewave of the voltage you want, and
the peak value is nearly the same as well.

But ... warning!!! ... in practice, you're dealing with a lot of
power here, and you need to be careful about things like
inductive kickback when you turn off the current in the
transformer winding. At least a start is to parallel each switch
with a fast-recovery diode, anodes toward common and cathodes toward
+340. And you must use switches--IGBTs--that are rated at plenty
high enough a voltage...I'd probably opt for 600V parts. Then you

are faced with driving the gates of the switches, which requires
some circuit that can follow the 340-volt excursions of the upper
transistors. It's not a trivial exercise.

: >An alternative is to supplement it with a small transformer or two.
: >If you can come up with a 50Hz transformer with a 30V 6A and a 15V
: >12A secondary, and 240V primary, you can hook the primary to
: >your line, then connect the 30V secondary in series with the primary
: >side and the 15V secondary in series with the secondary side of your
: >big transformer, all properly phased, so you get 240V-30V = 210V into
: >the big guy, and 105V out of the big guy, plus the 15V from the
: >little guy, for 120V output. If you don't need isolation between
: >primary and secondary, only stepdown, there may well be another way
: >you can hook things up to have them work well, perhaps not even
: >requiring a second transformer if the one you have has a split primary.

: The transformer is a standard US residential house transformer for
: converting the 240VAC line coming into the house to 120VAC (the
: kind in a grey metal box that mount outside the house). Beyond that,
: I am relatively ignorant. It was already wired up with a cord and
: European grounded plug and a metal outlet box with 4 US type grounded
: (three prong) outlets. The internals are unknown to me. I wish I
: was both more knowlegeable and experienced all around...

: I think I'd opt to try the chopper circuit first. So any circuit
: diagrams and tips would be very much appreciated.

I'd guess the little transformer would be cheaper than the capacitors
you would need in the switched circuit. And wiring it up would be
easier than messing with the switched thing, too. But...you're
welcome to do it either way or not at all, as you wish.

I swapped the 6LQ6s in my Dentron GLA-1000 for 31LQ6s, using essentially
the same maneuver. The 31LQ6s were cheap enough at the time (a couple of
years ago); the tubes I have are ECG brand and have worked very well. In
my case, I just used another 24V xfmr in series with the existing 6V
winding (31's were more readily available to me at the time).

I think the conversion you're talking about is a good idea. Just label
the amp internally so that some poor slob in the future doesn't kill some
6 volt tubes by putting them in 24 volt sockets...

I don't think so. I've used power transformers as high power audio
transformers for years. They roll off above about 10 kHz due to
parasitic capacitance, but they're fine out to 5 kHz or so.

Watch out for the inrush current - you can easy blow your ammeter if you connect directly to the lne voltage.

Use a variac and slowly adjust the voltage from zero. Monitor the current and shut down if it becomes excessive.

I agree with John - I think the transformer may be faulty, or you might be confusing "warm" with "hot".

Best Regards,

Mike

Source record: 79447

Our company radio club has a 2 meter FM voice repeater, with its antenna up on the 400 foot tower out back.

Since it is a major hassle to change or add anything to the tower, is it possible to share the antenna with a packet station 2 MHz below the repeater, allowing fully simultaneous operation of both? I thought duplexers could be used this way, but I am not sure and humbly submit it for comments and suggestions.

Thanks

Germanium transistors are subject to rapid aging, especially power
types. It's not a bad idea to get rid of them in any piece of gear you
want to keep.

Is it possible that Q412 means Q41, PCB 2, or PCB 4 , Q12 ?.
412 seems like a very big number, for a radio which presumably
has less than 400 transistors.

You can plot primary current versus applied voltage (no load on secondary) and get a really good idea of what's going on. If it goes up linearly at a very reasonable current, then rather quickly starts going up at a much steeper slope, it's likely that you've hit the core saturation point. But if the current is always excessive, and you get a pretty straight line of current versus voltage, then the transformer probably has shorted turns (or you are using it at a grossly incorrect frequency). Often shorted turns are also "noisy" in that the current at a fixed input voltage will suddenly change or jump around.

One good thing is that the transformer under load will have slightly lower core magnetization than with no load. But be sure that the load has no DC component! That makes things worse instead of better.

I have experienced that certain persons often try to replace good components when they don't know so much about them, instead of trying to sort out what is possibly wrong. The same madness applies, of course, for equipment using si-transistors, integrated circuits or what else. When they have sockets, it appears so easy to replace the devices, and I have seen several examples of persons installing sockets for IC's they expect to fail sometime in the future, and the only reason for this suspicion is that it is possible to install sockets.....

it was so much easier using tubes, and several so-called 'technicians' replaced a valve having low emission without checking bad cathode-, screen- or grid-resistors, the set worked better for a while and soon needed more service.....

I keep certain old small signal Ge-types for certain applications, have not experienced ageing problems. Believe Ge-type RF transistors have higher base impedance (smaller h11e) than Si-types.
OC44, OC45 (=CK605?), OC615, AF114, AF115, AF124, 2N1147 seems to work fine in simple applications for sensitive meter circuits. 2N398, 2N525, 2N1305, OC71, OC72,TF65, AC125, AC126 etc needs higher emitter-base voltage, but still solve some circuit problems over Si-types.

Source record: 79455
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.shortwave

For some classics, the value of the set will be ruined by indiscriminate modifications. ECG and NTE offer replacements for most of the early Ge PNP transistors. I have several solid state 1960s vintage Zenith Transoceanics, and seldom find the transistors to be a major source of problems.

Pete

>tom_bruhns@hp.com

Hello Tom and Patrick,

Thanks Tom for pointing out the in rush current and chance
of blowing Patricks multimeter if on low ranges.

Patrick if you do not have a variac as Tom suggests, then you
can use a 1 ohm resistor of at least several watts in series with
the primary winding. Then you can use your multimeter on the
AC voltage range to calculate the primary current .
current = voltage measured across the resistor/1ohm.

Put your voltmeter on a high range to start with.

Let us know how you got on.
Remember you are dealing with a lethal supply
no rough lash ups.

2147. PUFF device files and component info?

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-04 00:00:00 UTC
From: Luis Yanes <melus@esi.us.es>
Message-ID: <35EFE303.5156@esi.us.es>
Source record: 79459

I'm looking for info about PUFF software parts definition,
since I havn't any info or help file, but only a couple of
examples with:

lumped 150O
tline 50O 90D
qline 50O 130D
xformer 1.73:1
atten 4dB
device fhx04
clines 60O 40O 90D

I can guess the meaning, but how the coupled lines are
defined? And there is more parts?

The device files seems to be only a S parameter table.
Is there anyplace where could I find the most common
device files without having to type the whole table
from the datasheet?

> >transmitter to send out a fairly clean signal. Jonathan

As long as you never key it up into anything other than a dummy load you will be fine, if you actually connect it to an antenna and transmit you will become a criminal just waiting for the FCC to kick in the door and confiscate your rig, bank account, and temporary freedom.

No Ham who wishes to keep his license will assist you in building such a device as they would become an accessory to your crime.

Why not get a Ham license and actually communicate -- communication is a two-way process ... low-level broadcasting is frequently a waste of time since few are listening and fewer still will comprehend unless they can ask questions ... thus the popularity of call-in
talk radio.

Hate to burst your bubble, but you do have better options! Get a license and talk to the world -- two-way! :-) 73, DavidC AA1FA

Yeah, but to get that kind of attenuation you gotta have 230V *THREE
PHASE*.

So if you don't have the power supply, don't expect to get 48 dB of
attenuation. You might get only 30dB or so and you'll never bust a
pile-up with a whimpy amp like that.

```
Archive-name: radio/personal-brief-introduction

In an effort help ensure a poster's article reaches the appropriate
audience, below is a list of the rec.radio newsgroups. In most cases,
a group's name will explain its purpose. Cross-posting should rarely
be necessary.

rec.radio.broadcasting (devoted to the broadcast industry; moderated)
rec.radio.cb
rec.radio.info (periodic informational bulletins; moderated)
rec.radio.scanner
rec.radio.shortwave
rec.radio.swap (for buying, selling, and trading; not a discussion group)

rec.radio.amateur.antenna
rec.radio.amateur.boatanchors (tube-type communications equipment)
rec.radio.amateur.digital.misc (packet, pactor and other digital modes)
rec.radio.amateur.dx (long-distance amateur communications)
rec.radio.amateur.equipment (questions, comments regarding commercially-
built amateur gear; not for buying/selling)
rec.radio.amateur.homebrew (devoted to home-building ham gear)
rec.radio.amateur.policy (issues include code, restructuring, local
restrictions in conflict with FCC R&R)
rec.radio.amateur.space (satellites, meteor scatter, EME)
rec.radio.amateur.misc (any topic not covered in the above groups)

(At least two other English language radio hierarchies exist, prefixed
with "uk" (United Kingdom), and "aus" (Australia), in place of "rec.")

Again, cross-posting should rarely be necessary. Many times, a long-
running thread results from a single cross-posted article, and the
contents of such a thread drift further and further away from being
"on-topic" in the various NGs that receive each and every followup.

For more detailed information, see "Guide to the Rec.radio Newsgroups"
posted on the 15th of each month.

Jeffrey Herman (KH2PZ / KH6)

Any pointers to actual circuits? I'm able to build based on a circuit
but not quite skilled enough to build based on just a general description
of what to do ;-)

>Of course if your *loads* need 60 Hz (motors, clocks, etc) then this won't
>work....

No problem. I mostly will be running DC "battery eliminators" off it,
plus a few pieces of Ham gear with their own internal AC/DC converters.
How about an old Tektronics O-scope? Would that need 60Hz?

>It may be worth your while to consider rewinding it...

No can do. The actual transformer core and windings are encased
in a sort of plastic/epoxy which fills the entire metal enclosure.
I wouldn't think of trying to exhume it.

Any pointers on that chopper circuit would be greatly appreciated.

Cheers,

Patrick

>primary and secondary, only stepdown, there may well be another way
>you can hook things up to have them work well, perhaps not even
>requiring a second transformer if the one you have has a split primary.

The transformer is a standard US residential house transformer for
converting the 240VAC line coming into the house to 120VAC (the
kind in a grey metal box that mount outside the house). Beyond that,
I am relatively ignorant. It was already wired up with a cord and
European grounded plug and a metal outlet box with 4 US type grounded
(three prong) outlets. The internals are unknown to me. I wish I
was both more knowlegeable and experienced all around...

I think I'd opt to try the chopper circuit first. So any circuit
diagrams and tips would be very much appreciated.

Thanks,

Patrick

Hello Patrick,

Frequency is not the problem.

Your transformer could be faulty.
When you say "too hot" does that mean" warm" or
" burn your hand" if you left it there.
Warm is OK at no load.
Check the primary current with no load on the secondary.
100mA to 400mA is fine for a big transformer.
If you measure more than 2 amps of magnetising current
then it will feel very hot and is definately faulty.
The transformer should work on 50 or 60 Hz it is
not that critical. American equipment with mains transformers
are sold throughout the world, working happily at 50Hz.

Let us know how you get on with the primary alternating
current measurements, on the 240 volt (AC) side.

>stage, it was fairly clean, wich you also hear in the audio signal.

huh???

Yes, if you hook too narrow of a bandpass filter between your audio source and your transmitter, you'll reduce the frequency response. My personal experience has been that, as long as one keeps the audio levels (and deviation) down low enough to avoid distortion, typically-available audio sources won't deviate the transmitter out of the channel.

I suppose if you put a *really* narrow filter between the transmitter and the antenna, you could reduce your power output under modulation by filtering out modulation peaks. It'd have to be one hilatious filter! It would also result in severe distortion - probably well before you noticed the reduction in power. I fail to see what the use of a PLL in the transmitter has to do with this.

In any case, if the original poster is in the United States, he should note that the FCC's field crews have been very busy lately. For awhile, you could get away with unlicensed low-power broadcasting in the US, but that's no longer the case. I would suspend any plans until the ongoing microbroadcasting proceeding is concluded (probably this fall) and then see if you can qualify for a license. Or look up "bail bondsmen" in the Yellow Pages...

From the Drake List Reflector:

The nail color to get is called "Peacock Blue". Unbelievably, it is apparently a more-or-less standard color since I bought mine ~3 years ago in some beauty supply store in CA and saw some as recently as yesterday in Virginia, at a chain called Sally Beauty Supply. (It's my wife and daughter that go to these places, guys, I just tag along. Got that? I-just-tag-along.) Seriously, I think I've seen this stuff at Wal-Mart, etc. Really not hard to find, I don't think. It works well, in my experience. My fear was the bulb temp would discolor the nail polish. Not so yet. Again, this little trick works best *with* the existing clear blue filter, not in place of. It is kind of an equivalent fix to removing and reorienting the blue filter, placing the bleached out spot in another, less noticeable position. FYI, I think Drake still has original clear blue filters available if anyone wants to go that route. In my case, use of this nail polish trick, seen in QST years ago, yields a rich Drake blue hue to the dial and meter, maybe ever so slightly darker than original, but very very nice looking. I've done my R-4C but not the T-4XC yet and the difference is quite noticeable. Good luck.

Ford does. They have an RFI filter for the fuel pump. It mounts right at the fuel pump connector which is on top of the fuel tank - a real bear to get to.

Larry Bearse wrote:

Can anyone tell me the pin wiring for my Icom 737 ? I want to interface it to my P.C.
Its an Icom 737, but I am pretty sure it uses the same as most Icom HF rigs..

Any help would be appreciated.. Thanks..

Go to any search engine and search for "micro broadcasting"
It should turn up more info -- especially if you follow the links
--
than you'll know what to do with.

Every transmitter build acc. FCC rules will never give a fairly clean signal, but the effort to do so is a goal by it self.

You will have to put in several bandpass filter, but not to narrow becaus you want to have normal audio comming out of your radio.
If you make the bandpass to narrow you wil hear a strange sound comming of your transmitter, I can tell.
With a to narrow bandpass you also get problems with keeping up the max power output if the transmitter doesn't have a PLL, it will run out of the 'bandpass'.
Build several Tubetransmitters with max narrow bandpass in it, even between every stage, it was fairly clean, wich you also hear in the audio signal.

No. Sorry. Duplexers allow the separation for one receiver and one transmitter. It would not allow you to transmit two signals at the same time from the same antenna. This would not affect the receivers other than you would be splitting the gain or loss by 1/2 of the single receiver if you were using a splitter. Again not an advantage. 73

>humbly submit it for comments and suggestions.

Sure you can do it, but the combiner is fairly complex Basically,
you have to build another duplexer with a pass for the new frequency
and notches for both transmit frequencies. One notch, tuned to the
repeater transmit frequency has to be in the path to the packet
receiver, and the other notch, tuned to the packet transmit frequency,
has to be in the repeater receiver path. Some loss of repeater
sensitivity may result from this, but that's a price you pay for trying
to combine multiple radios to one antenna.

Hi David,

I agree with Gary. I actually did this about nine or ten years ago. The folks a Wacom fixed me up with another duplexer and it worked just fine. It was expense and took up twice the space, but it worked without noticeable loss in the repeater system. There was the duplexer losses in the packet system however.

Ge transistors are sensitive to contamination. If the transistor is made with contaminated fill gas, or if its hermetic seal fails, it will exhibit "rapid aging". On the other hand, a clean transistor with an intact seal will last very long time. I would not replace a working Ge transistor: there are all kinds of potential problems.

Most transformers made for use in USA are-or at least were- made for,
and were originally labeled for, 50-60 cycles. Unless you have one that
was
marginally built it should work OK at 50 cps although you might want to
derate it slightly. The sympton of abnormal operation should be excessive
heat.

In my opinion, you should avoid Ramsey. The kits looks nice, very complete with power supply, audio processor and so on. But I've heard lotsa places (hasn't tested myself) that the TX's themselves are no good, with poor audio quality and lotsa RF noise.

Yes, and the U.S. government specifies a limit for synchronous AM of a
FM broadcast transmitter here. (I want to say it's 2%) If the
signal's strong enough, it can still be rectified; the building I work
in is about 500m from a 100KW FM transmitter, and computer speakers in
the building play the FM station unless you filter them with ferrite
cores... and this is an unusually well-maintained FM transmitter..

The manual and source for PUFF are available for US$15 each at

http://www.systems.caltech.edu/EE/Faculty/rutledge/pufform.html

This looks like an extremely useful program with capabilities far beyond
the other inexpensive software that is available.

I wonder if there is a newsgroup or list server for PUFF? I searched
DejaNews, but only got music-related postings.

Best Regards,

Mike

Thanks. I'll take it to an electrician and have him
re-check the connections. I didn't set up the transformer,
which was already wired up with a European plug and US
receptical -- but it very well could be wired wrong.

Thanks for the tips.

Anyone out there ever started building soild state linear amp and never got round to finishing the project off for what ever reason, to expensive, lost interest, nagging xyl. You brought all the bits, mosfets included and there they sit unwanted, fretting, calling for a hot soldering iron and a tender loving heat sink. Don't let those mosfets down, they deserve a good home. I'm looking for 4 matched MRF150 mosfets untouched by human hand or soldering iron come to that. Priced somewhere below CCI price. If you have 4 and a willing to part with them then drop me a mail. I promise they will receive my unfaltering father-like attention and I swear to stick a good 50 volts up em!

A transformer needs 20% more iron in the core to avoid saturation at 50 Hz than it does at 60 Hz with the same number of winding turns at the same voltage. If the transformer *has* a sufficient core size, it will work at both frequencies just fine. But if it's built for 60 Hz operation only, the core will saturate on 50 Hz and the no-load current will be much higher than it should be.

Much equipment is built with transformers built for 50 Hz, and with parallel/series primary windings that can be connected for 120/240 V in. But it sounds like this particular transformer is designed for 60 Hz only.

I want to run a laptop computer from the batteries in an electric wheelchair. The laptop requires 24 VDC. The wheel chair is powered by 24 V (two series-connected deep-cycle 12 V batteries).

Since the battery voltage is correct for the laptop, I'd like to avoid converters or inverters. I'm aware that the motors may product power spikes and other bad things on the power bus that could harm the laptop, and that the battery charger may produce additional unknown voltages or noise when attached to the batteries.

What kind of filter or other protection should I used? (I need specfics about values of caps, resistors, etc. for any suggested circuits, please.)

Any suggestions and assistance would be greatly appreciated. Direct e-mail replies to voicebox@dnai.com doubly appreciated.

Thanks,
Dave

>

I wouldn't be so sure. From the seven most active hams that I can think
of in GI, six of those are ex-SSB CBers. SSB CB is illegal in the UK so
they are former pirates!!!

The one who was NOT an ex-SSB CBer (GI3OQR) was licensed in the 60's,
before the invention of CB. SSB CB (the illegal one) is one of the
greatest producers of HF hams in the UK today whereas FM CB (the legal
one) is probably the greatest producer of VHF hams. Now, I wonder why
that is ;-)

Since CB was introduced to the UK in the late 70's (initially
illegally), most new hams since that time have entered via the CB route.

The difference is that 60Hz is 20% different from 50Hz while
60Hz is 600% different from 10Hz.

If you're going to be using open or ladder line then 3/8 wave-length
on the lowest frequency of interest is about the smallest recommended.
Shorter than that radiation resistance drops very fast as well as a
rapid increase in reactance. The resulting losses incurred can be
substantial.

Your Mensa membership has just been cancelled, Cec. The percent-decrease from 60 to 50 is 16 2/3 percent. Percent change is always calculated using the original quantity (in this case, 60 Hz) as the base. Decrease / base x 100 gives pct. change.

Isn't a 20% increase over 50 equal to 60?

why not put it in the negative return? that way, you can avoid the high
voltage insulation requirement.

btw, you bought those transco relays from me... do they work out for you?

Wrong, wrong, wrong. The title of the thread is "Converting 50Hz to 60Hz".
That means the *original quantity is 50Hz*, not 60Hz. The increase from
50Hz to 60Hz is 20%. So much for math majors. Increase / base x 100
gives pct. change.

Hi Tyler,
Not sure what the galena is going to do in a regen receiver, but might try a supply house the vends to high schools, community colleges and universities. I bought a nice cubic inch chunk of the stuff as part of a sample kit when taking a geology course in college a few years ago. You'd be amazed when you demonstrate the talking rock to folks. Heh!

73,

Bob, KE6F

You might also check on some of the Arizona web sites for the stuff as it is basically junk in the tailing of old gold mines and the like along with iron pyrites (fool's gold) moderate replacement for galena in xtal sets..

yep. 60 is 120% of 50, but 50 is 83.3333333333333333etc% of 60. It's all how
you phrase the question. One way there is a 20% difference, the other it is
a 16 2/3% difference. In a comparison, I believe unless explicitly stated
otherwise, it should be in reference to the first figure given.

I do not agree! As an engineer who has designed many power transformers, please understand that this is a NONLINEAR device! In other words, if your magnetic flux reaches saturation, the incremental inductance drops sharply and primary excitation current develops large spikes, causing serious heat loss in the primary winding. Eddy current losses increase as well. It is NOT advisable to operate a 60 Hz transformer on 50 Hz! Smoke results.

> Raytheon Test Systems

Steve,

The 8510 system has two busses; an external one that is addressed by
the external computer and an internal one that is used to make a
system out of a bunch of seperate instruments.

Normally, the 8510 controls all of the system instruments
(synthesizer, s-parameter test set, plotter, printer, etc) via the
local (internal system) bus.

Your computer (should) connects to the main bus and addresses the
8510 system. Only when you want to talk to one of the individual
instruments do you use the pass-thru addressing. The computer stays
connected to the external bus connector but the pass-thru addressing
allows direct access to the selected instrument.

About the only time I have had a call to address an instrument
independently is when I set up a plotter to add my own labels and to
rotate the plot from landscape to portrait.

This is the best I can do from home without manuals in front of me.

98 +/- feet would be closer to 3/8 wave length, however, 85 foot would
work, but it would have a lower efficiency.

Would it reach saturation with such a small change in frequency, and
unloaded?

Power transformers make reasonably good audio tranformers over a limited
frequency range. They can't be that sensitive to the difference between
60 Hz and 50 Hz, can they?

I can see in running a power distribution plant, you'd be interested
having the proper transformer. But hams have been known to do worse
things and get away with it.

Best Regards,

Mike

>Isn't a 20% increase over 50 equal to 60?

Sure, if you choose 50 as the base (original) quantity. But 60 Hz is the
standard AC freq'y in the US, so we use that as a base for all other
comparisons. 50 represents a 16 2/3 percent *decrease* of 60.

To Cec: Note that 10 Hz represents a 83 1/3 percent decrease of
60 Hz, not 600%!!

>Wrong, wrong, wrong. The title of the thread is "Converting 50Hz to 60Hz".
>That means the *original quantity is 50Hz*, not 60Hz. The increase from
>50Hz to 60Hz is 20%. So much for math majors. Increase / base x 100
>gives pct. change.

Nice try, Cec, but I'm correcting *you*, not the subject line! All the
responses have spoken of running a x-former designed for 60 Hz on a
50 Hz line. The fellow I did a fol-up to said no over-heating would
occur. That's when I mentioned my "thought experiment" comparing 60
Hz to 10 Hz. 60 was and is the base quantity here.

To assist your short memory, the original poster inquired about
running a 60 Hz transformer in Europe, so that makes 60 the base
for all our calculations.

Remember, 10 represents an 83 1/3 pct decrease from 60 (not
600 as you claimed; 10 is certainly not the base, here.)

60 is the base, so there! Go sit in the corner now.

Hello,
Does anyone have any info on how to convert a standard carbon microphone for a hand held radio in aircraft (glider). I have a headset/boom mike made but need to know how to connect it and handle the impedance matching. The radio is a TERRA TPX 720.

Any assistance is appreciated.

Jon

Andre, Walt Maxwell in his book "Reflections" proposes using a dipole of length something like 105 feet and operating it with a tuner (I don't have the book here so I'm not exactly sure of the dimensions). As I recall, this configuration was used by many old-timers for operation on all the HF bands. Out of curiosity, I used NEC to compute the input impedance for this configuration at a typical height above ground, and on all bands the impedance was never extremely large. I would bet that this configuration was used by the old-timers because an impedance match could be achieved on all bands using a simple tuner. If you build such a dipole, you might want to feed it with ladder line and a W2DU choke balun to avoid high losses due to the high SWR conditions on some bands. 73,Bill N3WK

Hi there,

I recently acquired a bunch of L.C.D. sold for almost a buck
because the guy had lost the doc.

The L.C.D. is referenced EPSON EA-N20025AR then 5D4B66.

The ï¿½controller used is a pair of NEC ï¿½PD 7228 G, most
probably in a master / slave configuration.

I was unable to locate - on the net - any doc, nor for
the whole LCD, nor for the NEC part. Does anyone out here
have a clue or a data sheet ?

Thanks !

I bought a couple of narrowband 455 kHz IF filters, however, I found no information on them. They are labelled

CQ
33-455HT

and have 5 pins, 4 in a row and 1 separate pin.

I have some equipment to measure their transfer characteristics, however, I don't know the pin assignment. Various WWW searches turned out nothing.

I would be very grateful if someone could point me to any information, i.e. who is the manufacturer of this filter, where can I find data, what is the pin assignment.

Thanks

Gerhard

> clines 60O 40O 90D

> I can guess the meaning, but how the coupled lines are
> defined?

clines are specifies with Odd (Zo) and Even (Ze) Mode Impedances
and electrical/physical length.

And there is more parts?

atten - Ideal Attenutor eg atten 3dB
xformer - Ideal Transformer. Enter turns ratio eg xformer 2:1
lumped - Resistor, Capacitor, and/or Inductor
eg lumped 50o||1nH||1pF {parallel RLC}
lumped 10+l10-j10o {series RLC}
tline - Ideal Transmission line. Enter Impedance and length (mm or Degress)
qline - Finite Q tline eg qline 50o 90d 75Qd {Q=75 due to dielectric loss}
qline 20mS 90d 50Qc {Q=50 due to conductor loss}
clines - Ideal coupled lines. Enter Zo,Ze and length or electrical length
device - Read s-parameter file data.
indef - Indefinite s-parameter generator. Converts n port s-parameter file
to n+1 port device. Specify file name as in device.

> The device files seems to be only a S parameter table.
> Is there anyplace where could I find the most common
> device files without having to type the whole table
> from the datasheet?

No thats the only way I know how.

F2 TAB - Toggles Smith Chart Z-Y
F3 TAB - Extends Parts List
F5 - Toggle Colour
F10 - Help
Alt-S - Expands Smith Chart

I hope this helps to get you started. A better program is APLAC (Search for it using APLAC) there is quite a useable demo with manuals available on the web. It can cope with most things RF and Microwave wise.

Okay, you got my curiousity aroused. Why do you need galena
for a REGENERATIVE receiver? It uses a gridleak detector.

Galena one form of raw lead ore. Check shops that cater to
rock collectors. Or, contact Antique Electronic Supply in Tempe
AZ, they will sell you a galena detector that is mounted in a special
low temp alloy and ready for mounting in a detector.

I can't offer a webpage, but I can offer two paper sources you might want to check.
The first is the Proceedings of the Central States VHF Society. They featured
a number of very good VHF preamps in one volume of that series. The ARRL
sells the books, a note to them may localize your search to the particular volume.
The other book would be the VHF/UHF DX Book sold by the RSGB.

Ok, unless the nomenclature is different over there, 2PSK should
be the same thing as BPSK. That means there are two symbol
states for the modulation, 0 degrees and 180 degrees. You can
receive this with just an ordinary FM discriminator, but you'll
gain about 3 db of sensitivity by using coherent detection and
a PLL, either a Costas loop or a squaring loop would do.

Baseband clock recovery will depend on the baseband coding
used. It probably uses Manchester biphase coding, but it could
use something else. You need to find out what baseband coding
is being used before you can design the clock recovery and
data slicing circuit. It is likely that the circuit used in the TAPR
BPSK satellite modem would work with suitable loop filter time
constant changes. The JAMSAT modem would probably work
too. Those circuits were published in US magazines several
years ago. The JAMSAT circuit was in Ham Radio Magazine,
I don't recall where the TAPR design was published.

It would also be pretty simple to program a PC to decode the
signal from the discriminator using a sound card. There's probably
some software lurking on a website somewhere you can download
to do that.

> amateur radio?

True, but then why not seek an internship at a legitimate broadcast station where you will also have enough listeners to justify your efforts? You might even find a radio (or even cable) station that will give you your own off-peak air time. Such efforts could lead to a professional career. BTW: You can also "broadcast" music on the Internet, and it looks as though such broadcasts have a big money future!

We seem to be suffering enough from anarchists already: social, political and physical violence of all sorts (bombs, greedy unions, polluting businesses, lying politicians, CBers flouting power limits, etc.) ... do you really want to add yourself to their numbers?

Civilizations have always failed when too large a number of the population decided that laws and boundaries didn't apply to them -- the result, after brief anarchy, has always been tyranny ... where raw force is imposed to enforce laws ... often arbitrary in nature.

If you think about it carefully, you will discover that the small choices we each make can have larger consequences down the road ... selfishness is contagious!

2262. Re: Converting 50Hz to 60Hz for transformer???

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-07 00:00:00 UTC
From: Roy Lewallen <w7el@teleport.com>
Message-ID: <35F44C5D.94EC29CE@teleport.com>
Source record: 79365
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.misc

This has been an interesting and educational discussion. It occurs to me that if a manufacturer wanted to make a transformer as inexpensively as possible, he'd use the minimum amount of copper and the minimum amount of iron that he could get away with. The rated current would establish the wire size, but the smallest number of turns would be dictated by the amount of magnetizing current that could be tolerated. (Although the magetizing current would heat the wire, it would probably be quite a bit less than the load current. But increased magnitizing current would increase the flux density in the core.) The iron could be reduced until saturation begins to occur under full load. (The flux density under full load shouldn't be a whole lot greater than under no load.) So in a minimally designed transformer, both the number of turns and the amount of iron would be decreased until the cheapest combination is found that has acceptable heating. The heating will definitely be greater at 50 Hz than at 60 Hz. A small transformer used in expensive electronics equipment might be designed to handle 50 Hz and have a dual primary, so that one transformer could be used for all applications. But if the market is competitive, no overdesign could be tolerated, and a transformer for a 60 Hz application would be designed to get good and warm at 60 Hz, and probably quite hot at 50. I have a good example, a 13.8 volt 15 amp power supply with linear regulator. This is a very competitive market, so every component is carefully designed to just meet the requirements. The power transformer in this supply gets too hot to comfortably touch when the power supply is running without any load. I'm sure that it would be nearly smoking at 50 Hz.

Melt???? It's already a liquid.

If you're referring to the boiling point of ethyl alcohol (ethanol), it's
173.3° F (for _pure_ ethanol).

Well it does melt but only if you freze it first. Yes it is possible to freeze the water out of a water/ethanol mixture but the efficiency isnt very high. Your best bet would be to set up a still unless you just want to make your mix a little bit stronger. A water/ethanol mix will allow the water to freeze before the ethanol making a stronger mead for example, but the ice left over will still have some ethanol which you should distill. buy a pressure cooker somewhere and fit a copper hose on the top (approx 10 feet long or so) and then boil the mixture that is left over from the freezing just be sure you dont take the methanol (bp 67 C or so) and only take the ethanol (78 +-) but that wont be able to make pure ethanol just about 80% likely. The actual max for distilling is 95% which is an azeotrope. This is probably more info than you wanted but it should help.

> Oh, sure... but what was the last time you saw frozen alcohol??? :)

The original post didnt specify what kind of alcohol. Alcohol is a term which describes many compounds, for example, ethylene glycol (antifreese) is an alcohol. Some of the higher order alcohols are solid compounds at room temperature. As an example, consider C12H25OH , Dodecyl alcohol. It has a boiling point of 491 deg F, a freezing point of 73 deg F, and is insoluble in water. More input is required to give a precise answer to the original question. I'm also not really sure if he is in the right group. Is there a sci.chem group?

> The only filter known to REALLY WORK is.....
> Trade that Ford in and buy yourself a DODGE!

I used to like MoPar products until I took my Renault Alliance to a Dodge dealer for repairs; the dealer did severe damage to the electrical system while replacing an air-conditioning compressor and *charged us for the repairs*. When we called Chrysler to complain, they said they had no influence in the matter because it wasn't a factory-owned dealership. They could not name one factory-owned dealership anywhere in the world.

Basically, their products are good cars with plastic parts that break easily and NO WARRANTY because their stance on "factory-owned dealers" means they don't have to provide one. Put a noise filter on the Ranger instead.

dx 390 radio shack sw reciever with
box manual ect....almost new works well and no blemishes

$70 +shipping

<2>
mfj 451keyboard keyer with keyboard,
wall adapter, manual, box, keyinput

sells for 99 in the mfj catalog, street retail?

$45 + shipping

<3>
mfj 564 iambic key paddle wired with
a stereo jack to be used with any iambic
keyer to get dits on one paddle and dahs
on the other

$29 +shipping

<4>SOLD
IC 22S

<5> SOLD
radio shack digital power meter.

<6> SOLD
tug 8

<7>
d104m6 mobile amplified mike
7 volt battery cage broken, you can
get another from astatic for $2.00
no connetor for radio

$20 shipped

<8>
I also have about 2 dozen 4 wire
mike cords. These are the heavy duty
belden cables that I bought surplus cheap!
I will pass the cheap on to you

these normally go for 9.95 each

$3.00 per cable shipped

<9> sold

<10>
matched pair of mrf497's I was going to build a radio
with high output but the idea fizzled...***note these are the
high output transistors that are used in the hr2510/hr2600/htx100
high output mods****
I also have a matched pair of mrf492's that I was going
to build into a 6m amp, but am going the route of a
larger output radio.

497mp $45
492mp $45

<11> Radio Shack scanners,
pro 2035 1000 channel scanner with excellant recieve
25-512/760-1300mhz
$200

pro 2045 200 channel scanner 29-54/108-174/216-512/806-1000mhz

$120

or I will take partial trades
I am NOT opposed to trading up or down
or buying outright

looking for....

KAM version 7 or later with software/cables

6 meter radio will consider allmode

10 meter FM ONLY radio ie azden....regency 88
2kw or better tuner with wire/and dual coax outputs
and meter

ham IV or bigger rotator

I can be dealt with, if you have trades, let me know

km5rt@ticnet.com
I LOVE THIS RADIO STUFF!! remove the read47usc227beforespamming
to reply. I hate spam, and will delete it. thanks
Pursuant to 47 USC 227, any spam, harrassment, or any type of
unsoliceted mail will be forwarded to my collection agency
for a $50 fee per message. This modest fee recovers the
time lost reading the meaningless message, the brain time
to figure if it was meaningless, the disk space used until I
had time to figure, and the time and effort that it took to kill
the OFFENDING message.

If you like CW use it! If you will not be doing CW on the ham bands, 13 WPM is probably fast enough for the test. 20 WPM will only get you 75 khz of space for voice for MUCH time and effort... you weigh the effort to gain ratio...it is YOUR choice!
I am presently active on. 160-10 meters ssb voice,packet,SSTV and fm where allowed, 6mssb,6mfm,2mssb,2mfm packet,2mfm simplex, 220fm,432ssb,440fm,440fmpacket and whatever else I can find.

Never mind all this math jazz. From one who has been there let me tell you that using an american 60 hz xformer on 50 hz is asking for trouble.

I lived in Jordan for 2 1/2 years. The major concern people had - was the failure of american equipment designed for 60 hz and operating on the local 50 hz system.

So play with your math but don't take american 60 hz equipament into a 50 hz country.

Yep, looks like directly modulating the VCO
would do it. Many older model PLL CB's can
be had for almost nothing here in the US and
are a good source for experimentation on the bench.

>unless you get some kind of special permission

Nahhh. Try it the other way around -- stick the output
of a T-base2 network card into a wideband amp.
Now THAT would really cause something.... :-)

What was the failure mode? Let me guess - burned out transformers!

Well, take equipment that is running pretty close to the limits, add the
daytime temperatures in Jordan, and drop from 60 to 50 Hz.

Actually, I'd bet many would fail from the first two. Add the third and
you've got toast.

You are absolutely right. Won't work.

> I am looking for a 4 KV+ @ 1 Amp around 8 Hy choke. Anyone help?

Yeah, put the choke in the negative line so you don't need the 4KV+
insulation. Alternatively, place the choke on insulators of sufficient
quality and separation so that it won't arc over.

A friend used this trick to milk a few more months' use out of a
partially shorted modulation transformer for a 5 KW AM broadcast
station. He basically unscrewed the transformer and slid a board
between the transformer and the chassis.

What can I say, it was a college station and they could afford a board
but not a transformer or an FCC-licensed engineer.

Jim N6OTQ FWIW, recall the difference between a transformer and a choke --
the secondary.

I want to build an external transportable battery supply for my laptop computer. I have a rechargeable 15 volt battery from an old Motorala handheld 'brick' (was used in the old vhf mobile telephone service about 10 years ago). My computer input either from a power supply from the wall or from a car cigarete lighter takes 12 volts. Could I safely use this battery? (Probably not, so on to my next question---) I want to convert the 15 volts to 12 volts to safely use it. In my old radio building days (about 20 years ago) I knew there was a way to do this, but now I am not too sure how to use the Ohms's law to convert down. I do know it may only take a couple of resistors and maybe a diode or two (OR am I talking ancient equipment here????) Can anyone help me out with a circuit to do this? Would be appreciated!!!

BTW: For those curious, it seems my internal batteries are always giving my low battery indications after about 20-40 mins of use (even tho manufaturer suggestions say 1-2 hours. Tho most of the times I can use the power cord, there are times when it just isnt convenient to do so (like when I need to do some work and will only be on for about 30-45 mins).

Any help is greatly appreciated in advance.

You can either post an answser here, or (preferable) email to the following:

John Murphy
murphy@warp6.cs.misu.nodak.edu

The reason for posting from a different email is that the one I check all the time wont let me post to the newsgroups (tho I can read them). So I use a backup email address for this. Again, thanks in advance for any help anyone can give.

John Murphy

2290. Re: DC Power conversion 15 volts to 12 volts

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-08 00:00:00 UTC
From: aci6@aol.com
Message-ID: <1998090816523400.MAA20715@ladder01.news.aol.com>
Source record: 79295

Hello John,

I would not attempt to use resistors to accomplish this. As the current varies, so will the voltage provided to the computer. This is not good!!

A fairly simple way would be to string 4 1N4002 diodes in series with the battery. The voltage drop across each diode junction is about 0.7 volts . . . sooo, 4 times 0.7 = 2.8 volts. And, 15 minus 2.8 = 12.2 volts. If 12.2 is too much, another diode will lower it to 11.5 volts. These diodes will handle up to an amp. If your computer draws in excess of 0.75 amp max, I would use diodes with a larger current rating. BUT, test this arrangement BEFORE you use it with the computer to be sure that it works properly. One way to do this is to find a 12 volt automotive bulb that draws approximately the same current as the computer and use the bulb to test the circuit while measuring the voltage across the bulb.

Also, for safety, I would be sure to FUSE such an arrangement and it MAY be necessary to put a high value resistance across the output of this arrangement in order to be sure the diodes are forward biased (conducting.) I say this because I have not tested such an arrangement when little or no current is drawn and I would not want you to damage your computer by applying the full 15 volts to it even at miniscule current levels.

Alternatively, you could use a 7812 three terminal 12 volt regulator. This may be a better arrangement. This regulator will handle 1 amp also but it will require a heat sink and other components (capacitors) for bypassing the input and output, etc. There are other similar regulators that will handle greater (or lesser) current levels. But, the 7812 needs about a 2 volt "margin" to work properly. So, if your battery voltage drops below 14 volts, this method may suffer.

Regards,

Bill

Even though you *might* be able to connect to the battery directly, the easiest thing to do is to use two power silicon diodes in series to drop the voltage by 1.4v to 13.6v, which is about what the car would provide when it is running. BTW most battery specs are made assuming the drives are powered down most of the time.

VMOS? I thought that was dead, or maybe you have some old parts on hand?

As I recall Pye inverters (Cambridge etc) were much higher than 400Hz,
more in the annoying mosquito range. If you use a separate oscillator you
should have the luxury of tuning for efficiency.

Just to add my two cents here...
The "intern" does not have the privilage of choosing his/her program material--they must follow a rigorous routine of bulking carts, filling out paperwork, doing dull production work on the less important soundbites their news dept captured that day, and very often, also doing janitorial duties. I know--I've watched it all go on at a couple of stations where I engineered. These poor boys and girls will have a long way to go, often months, before they even SIT behind a live mic, and once there, they will be locked into the station's playlist, told what to say and not say, and be basically about as limited as they were before they got the hairbrained idea that they wanted to do radio.

Those days of opportunity, of doing your own show (and even getting paid for it) have pretty much ended after folks like Karl Haas got their start that way--that was when radio was still purposed to do community good, as opposed to profit at all cost.

>We seem to be suffering enough from anarchists already: social, political
>and physical violence of all sorts (bombs, greedy unions, polluting
>businesses, lying politicians, CBers flouting power limits, etc.) ... do
>you really want to add yourself to their numbers?

All of what you listed above are a SYMPTOM of big corporate-controlled government, not the cause of it. Politicians will always use these outbursts as justification for increasing the size and invasiveness of government, and it serves their end effectively because frightened people will ALWAYS gladly give up freedoms when promised personal safety in exchange. This was the same tact Chancellor Hitler took in the '30s...let the lawless reign for a period, then bring in tyranny as a "solution". Look where it got Germany.

>Civilizations have always failed when too large a number of the population
>decided that laws and boundaries didn't apply to them -- the result, after
>brief anarchy, has always been tyranny ... where raw force is imposed to
>enforce laws ... often arbitrary in nature.

Civilizations fail because their populous lose faith in their form of government. Furthermore, overpopulation causes friction, and this causes people to act like babies and wail and complain to their government for "protection" and more laws. Rational people do not need external laws--only children do --because rational people can foresee consequences while children do not and need to be forced to control their behavior. Our country has become a big kindergarten because of the sheer number of impudent moaners and complainers who often wail frivolously, with the result being a net of laws so complicated--so all-encompassing --that they go way beyond what our forefathers would have allowed.
We need to stop giving birth to so many babies. It's clear to me that in low population areas, the laws are fewer and less hostile, while in cities, laws are strangling people. Just try living with "alternate side of the street parking" laws, where, if you don't get out religously every day and move your car at 6am, you get a $100 ticket--the appeal of which, is a costly, frustrating dead-end, mired in municipal red tape.

>If you think about it carefully, you will discover that the small choices
>we each make can have larger consequences down the road ... selfishness is
>contagious!

While I commend your concern over the "big picture" and your effort to look to the future, I feel that you've looked more at symptoms than true causes, as often the causes are more subtle, whilst the symptoms receive the blame. We have too many laws. Now, pertenant to broadcasting, it's clear that those laws are there to protect the interests of big business, not the people, equally and without prejudice. In fact, nearly all laws, are design to protect the "New King"--corporate enterprises and their government servants. Insurance protects the New King from lawsuits by the populations--so we are required to possess it. Broadcast licenses ensure a limit to the kind and quantity of competition that NAB stations can tolerate. By making this a "rich man's game", no one with fresh ideas and a motive other than the accumulation of obscene quantities of money can get on the air.
This country needs philosophical guidance, which it is so painfully lacking.

And there you have my two cents, at a cost of fifty-seven cents to me, due to monetary depreciation...

So you mean that if it's discovered that a ham has assisted in
building a pirate TX, he is responsible for the guy transmitting, and
he'll loose his licence? That's a pretty heavy reason NOT to bother
with getting a license in the beginning, I say.

Longer than an 80 meter dipole to have the feed impedance higher than, and not less than, 50 ohms at all 80-10 meter frequencies...make it say 138 feet total (69 per side).

Then feed it with 450 ohm ladder line to the shack. Use a current 4:1 balun (e.g., RadioWorks Remote balun) just outside the shack and use but 10' of coax into your tuner in the shack. Feed the coax into the unbalanced output of your ATU.

Do not use the balun that is fitted inside your tuner unless you are running very low power. Chances are it is a SMALL voltage balun, and chances are it will get hot and lossy with the high SWR you will have on certain bands.

For anyone who has a FT-890 or FT-990. SP-6 Yeasu speaker with Timewave DSP-59Y digital signal filter, matches speaker. This is a great upgrade for these radio's or any other transceivers. Asking $335 plus shipping Speaker was $125 and DSP-59Y sells for about $359 or higher.

Ron Higgs wrote:
> Then feed it with 450 ohm ladder line to the shack. Use a current 4:1 balun

Hi Ron, here's what can happen. Let's say the antenna impedance is 50 ohms.
The SWR on the 450 ohm ladder-line will be 9:1. If the ladder-line is
1/2WL, that 50 ohms will be repeated at the balun. With a 4:1 balun
it tries to take the 50 ohms down to 12.5 ohms. The balun is designed
for 200 ohms and sees 50 ohms which equals high current and losses.
The tuner sees 12.5 ohms which equals high current and losses.

Because of the above, I use a 1:1 choke and feed my antenna
system at a current maximum point for a near perfect match without
a tuner.

Anybody know where I can get/read Fox Tango Newsletters. I have a Yaesu FT101F and any info/tips on this thing would be great. It's a bit old, needs alignment and has recently developed a problem on 10 meters (Very Low power Out 8 watts). Power out is OK on 15, but seems to be getting lower and lower. Power
out is normal on 40 and 80 meters.

> use, it is always much higher.

Not true Ron. Any of the infinite number of antenna impedances that yield a 9:1 SWR with 450 ohm ladder-line will give a perfect 50 ohm match at the current maximum point on the feedline. And any ladder-line SWR between 4.5:1 and 18:1 will yield a 50 ohm SWR less than 2:1. ALL possible feedpoint impedances for a 130ft dipole will cause the 450 ohm ladder-line SWR to fall between 4.5:1 and 18:1 on ALL HF ham bands.

4:1 baluns don't handle reactance very well either. They are designed for a resistive 200 ohms. A 4:1 balun on a non-resonant antenna system is just not a good idea. They generally never see their 200 ohm design impedance.

> I do agree that if the antenna impedance were ever lower than 100 ohms then a
> 1:1 balun would do the job.

Then you agree because a 130ft dipole fed with 450 ohm ladder-line shows an impedance less than 100ohms at the current maximum point on ALL HF ham frequencies.

> Look at this set-up with ELNEC, EZNEC, or other modeling program to see what I
> mean.

That's my advice to you. But it has to be EZNEC 2.0 with the transmission line modeled as well as the antenna. Or you can look at my web page to see what I am talking about. I don't use a tuner and I don't use a 4:1 balun and I have a near perfect match on all HF ham frequencies.

There are several types of basic receivers that are not superhets. Crystal sets are completely
passive devices, no amplifiers or power sources other than the received signal.
Simple sets include TRFs (tuned radio frequency), Direct Conversion, Regens,
Reflexes, etc.

I guess this is home-brew. I put together a repeater with Hamtronics kits, the R451 receiver and the TA451 transmitter. I also have a motorola amp on the transmitter and a rf concepts pre amp on the reciever. I have a Sinclair CM-351 duplexor.

Anyway, here is my question. Everytime I tune the transmitter to put out anything over 15 watts measured at the duplexor output, the rf seems to get back into the reciever and keep itself keyed and howeling etc...

Under the 15 watts it works great.

I'm sure you will need more info, but this is a start.

Any ideas.

FYI, I removed the pre amp, still had the problem, I tried a different tx amp, same problem.

Hi Danny, have you read the paper on the subject that exists on W7EL's
web page? The choke impedes the flow of common mode current and the
common mode currents are the same on both sides of an unbalanced
tuner. In other words, the choke doesn't see the differential
50 ohm impedance. It sees the common mode currents and that
impedance is usually an unknown.

Knowing the approximate resistance of the choke, can the voltage
drop across the choke be measured and the current and impedance
calculated from those two know values?

Hi all,

We use sixteen of these amplifiers (each with 4xMRF150s)
as part of a HF radar. Although they are designed to
be broadband across HF, we are only getting maximum
power out between 20-30MHz. Below 20MHz the signal is
very distorted, and the power drops accordingly. It
appears to be an impedance matching problem, and the
frequencies we most want to use are 8-20MHz.

So my question -> has anyone else built these amplifiers
and found the low frequency response to be poor? If so,
what did you do about it?

If you're interested, we have lots of photos of our
amplifiers and radar hardware at:

That's not the idea behind Amateur Radio. The ideas are to promote the radio art and the goodwill which the license provides. To help your fellow man if he's in trouble and to assist in the advancement of electronics.

If you were talking about a Ham rig, I'd have all kinds of
recommendations. For a laptop, I mostly have questions.

First, I'd verify what the computer really needs. What does the
manual say? Does it run directly off the cigarette lighter socket?
When you're talking about automobile batteries and systems, 12 volts
is not exactly 12 volts.

If the computer will run off the cigarette lighter while the engine is
running, then your "15-volt" battery may be fine as is. Auto ignition
systems commonly run 14 to 14.5 volts when the engine is running.
Long after you've shut the engine off, the battery settles down to
anything from 12.7 to 13.2 volts. So "12 volts" is a nominal value
at best.

If your 15-volt battery is indeed 15 volts and your computer indeed
needs 12 volts, then the safest way to connect the two may be to use a
3-terminal voltage regulator. Several kinds are available that have
different current capabilities. 12-volt, 1-Amp regulators are easy
to come by, and the mail-order houses have them up to 3 Amps.

One regulator will provide reliable 12-V output with no additional
components.

But first try to determine what voltage and current you really need.

2323. Help me design an active bandpass filter

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-09 00:00:00 UTC
From: Stephen David Hodgkinson <scotia-technologies@zetnet.co.uk>
Message-ID: <19980909090015185911@zetnet.co.uk>
Source record: 79313

I require two active bandpass filters with very narrow bandwidth.
The first is at 460Khz, with a -6dB bandwidth of 700Hz, the second is
at 5Khz with a bandwidth of 250Hz.

Both active filters require to have at least unity gain, though I
would prefer some amplification too.

I wish to construct these filters using only standard components please.

Any pointers to both schematics / websites and also to the formulae
for calculating component values for centre frequency and bandwidth
would be greatfully received.

Cheers
Steve

Have used several Cambridge / Continental FM25 series radios...Concur the inverter freq is in 1500 - 2khz range BUT varies with current load on the inverter (as many inverters and SMPS do)....So I'd recommend TRY your circuit and see what ya end up with....trim it from there (my choice of "engineering" with parts ...."from the box" :)

Yes, if your intent is to break the law then I guess it doesn't make a lot of sense to get a license first. If you plan the shoot someone with a gun I guess it probably wouldn't be a good idea to get a license for your gun either.

Hi John,

With no knowledge of commercially available DC to DC Converters manufactured for you application I suggest the following:

Go to your local public library and look up ARRL publications.

The Radio Amateurs Handbook has a chapter devoted to power supplys.

There is a section of this chapter that gives the info you desire called "DC TO DC' converters.

I would suggest that you follow this circuit shown with a 3 Pin 12 Volt regulator circuit also shown in this chapter.

Anyone know of a commercially available 12 vdc to 15 vdc converter??

No, it means that people of character choose to do the right thing, and
people of poor character choose otherwise. Witness Bill Clinton ... is
that the model you choose?
Ham radio has been a hobby that depends on cooperation, voluntary obedience
to rules and laws, and the rejection of those who intentionally break rules
... it has been a nice hobby for a long time ... the reason we now need to
call for the FCC to re-enter with aggressive enforcement is because so many
people of Clintonesque character have invaded the hobby and are tearing it
down around them ... it is sad.

The LM338K Three terminal adjustable regulator will, with proper heat sinking, provide up to five amps of current. The external components required are minimum, and it is a simple circuit to construct. The data sheet available from most vendors has a suggested circuit. This would work great for you, with the added value of being able to power 9v and other levels.

: I wish to construct these filters using only standard components please.

Though I'd recommend a "standard" mechanical or crystal filter on 455kHz instead of an active filter, for that very narrow percentage bandwidth, there is a way you could resonably do the job: you can mix 460kHz down to, say, 0 kHz, using quadrature mixers; then pass the I and Q channels through identical bandpass filters; then remix back to 460kHz. You have to do two filters, but they will have half the resonators as the one at 460kHz would have, and they will be at very low frequency. You didn't say how fast the filter response should fall, nor how far, as you go beyond the 700Hz bandwidth, and that's important...

: Any pointers to both schematics / websites and also to the formulae
: for calculating component values for centre frequency and bandwidth
: would be greatfully received.

You might do a web search... I'm sure you'll find lots. And I'd think that Burr-Brown has some good ap info on their "Universal Active Filter" product line on the web. The state-variable configuration they use is known for low sensitivity to component variation.

My 52 cents on this thread:

One does not need to have intent to break the law simply because the person has no license. Some people drive motor vehicles without license, simply because their minimum wage employment does not pay enough for them to afford insurance. Some people broadcast without license simple because the FCC won't grant them one. Some people own handguns and even automatic weapons without license because they don't want the government to confiscate their only means of protection from tyranny, when that dark day comes. Being without license is the basis of this country--the very reason we broke from England. RIGHTS ARE NOT LICENSABLE.

Does anyone know of any homebrew projects for making an intermod filter?

I just set up a dualband super copper cactus (homebrew of course) and am using my 2m/70cm HT on it from in the house. But, I'm getting really bad intermod on 2M and I think it is from the 150MHz pagers band. It sounds simalir to a modem connecting. Anyway, I'd love to try to homebrew a filter to fix this problem, but I don't know of any plans or if it is even a realistic homebrew project.

Hi Cecil,

The poster asked for a way to use an 80 meter dipole on 80 through 10 meters!!!

You are correct for an 80 meter only antenna BUT....for an all-band the antenna impedance is NEVER 50 ohms if you make it longer than your lowest frequency of use, it is always much higher.

That's why you can make an all-band with a longer than 'lowest frequency resonant' dipole and use ladder line and a 4:1 balun.

I do agree that if the antenna impedance were ever lower than 100 ohms then a 1:1 balun would do the job.

Look at this set-up with ELNEC, EZNEC, or other modeling program to see what I mean.

Regards, Ron

2341. FS B+W Coils

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-10 00:00:00 UTC
From: Larry Asp <larry.asp@sympatico.ca>
Message-ID: <35F730E4.493C@sympatico.ca>
Source record: 79246
Cross-posted to: rec.radio.amateur.boatanchors,rec.radio.swap,rec.radi0.amateur.equipmment,rec.radio.amateur.homebrew,

I have a box of B + W coils, consisting of 10MEL, 40MEL, 20BCL, 20MEL, 20JCL, 20JVL, 40JEL, 5JCL, 40JCL,TVH Base, TVL base all in decent shape. Also I have another small box of coil parts that may be usable with some repair or yeild parts for other coils etc.

I would like to sell all this as a package lot for $40.00 plus shipping.

Nope, it's not. It is a balanced "L" feed with a bead balun. The balun
is only seeing R50 +/- J0.

I thought I had sent you a picture of the tuner Bob.

I'm afraid this isn't what the balun is seeing. 50 + j0 is the impedance between the inner conductor and the inside of the shield. The balun doesn't see this. What it sees is the impedance looking both ways along the outside of the coax. In the case of an unbalanced tuner, this isn't changed by the tuner, so balun operation isn't improved by putting it on the input side of the tuner. I've never done an analysis to see what happens with a balanced tuner, but suspect that it doesn't drop the common-mode impedance (the Z on the outside of the coax) that much. In any case, the balun isn't dealing with 50 + j0.

2348. Gauge/insulation/type for end-feed random wire

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-10 00:00:00 UTC
From: Will White <wcw@asu.uswest.net>
Message-ID: <35F7A4E4.5CC28F3D@asu.uswest.net>
Source record: 79253
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew,uk.radio.amateur

I am putting up a 80-100' end-fed random wire for 80-10, feeding through a good tuner (MFJ-949E) and want advice about the best type of wire to use.

Issues I need to address are: stranded vs. solid; insulated vs. uninsulated; copper vs. tinned copper or silver-plated (sic) copper. I am 'shooting' for invisibility, or as near as I can reasonably come to that goal.

The wire will run out the shack, up a tree, across to another tree, and down. I suppose I should use insulated wire, for weather resistance and concealment, but wonder what amount of loss that will add.

How much difference will using expensive high grade antenna wire make? Oh, I will use 24 ga.

How much benefit would using an automatic remote tuner like the LDG or such like yield me? I.e., in terms of relative losses and RF feedback/RFI?

Will White, KD7BFX

Roy,

My tuner is balanced. I am using a variation of Rick Measure's design.

```
---------------(COIL)----------------->
| |
| |
------------------| |
>----(BALUN) (CAP)
-------------------| |
| |
| |
--------------(COIL)--------------------->
```

I don"t believe there is any noticeable common mode current as the
balun is connected directly to the coils. There isn't more that 1/2"
of coax exposed before the balun. And, by the way I'm using 90 beads
(I know that is over kill, but had them on hand).

Danny

Cecil,

See my posting to Roy's comments. I have read Roy's paper, however, that (as I understand it) deals with using an unbalanced tuner/ balun combination which I am not using.

I installed Ford's RFI filter on a '91 Explorer fuel pump and it dropped the noise level on 40M about three S-units. It's a bear to drop the tank to install it, but the result was well worth the trouble IMO.

The most likely reason is that as you peak the exciter chain, either part of the chain breaks into parasitic oscillations or the xmit spurs/sidebands get high enough to affect the receiver. If you can get a spectrum analyzer, you can see this happening as you tune up. Since I'm not familiar with the Sinclair CM-351 or your expertise, I'll only suggest checking the duplexer tuning, you shouldn't tune it unless you know what you're doing. You should verify the shielding between units and the coax shields are tight, and that the power supply inputs are adequately bypassed/RF suppressed at the receiver and transmitter.

Good luck,
Carl WB6YFZ

There are two general types of filters suitable for this sort of problem.
One type is the bandpass filter. This only passes signals in the amateur
band unattenuated, and rejects all others. This can be a good solution,
but getting 4 MHz bandwidth with steep skirts isn't exactly a walk in the
park. And you *will* have some insertion loss on 2m. The interdigital type
filters work fairly well for this, but they get pretty large at 2m. Go to
www.wa4dsy.radio.org and follow the links to a Java applet which will
design an interdigital bandpass filter for you.

The other sort of filter which works well against pager crud is the band
reject filter. Pagers are confined to a fairly narrow segment of VHF-Hi,
and laying a good strong notch over that segment will keep them from
overloading the front end of your HT. You don't care much about passband
shape with this sort of filter, a few overlapping helical notch cavities will
do just fine, and they'll have virtually no insertion loss on 2m. Helical
cavity design is well covered in the RSGB's VHF/UHF Book. You just
Tee them in the line between the antenna and the radio. (Simple coax
stubs can be used too, see the ARRL Handbook.)

>amp, same problem.
>
>-Tim

Tim, the first thing I'd do is look at the transmitter on a spectrum
analyzer. Hamtronics Tx strips are fairly infamous for generating
spurs when simply peaked for max output. You need to tune it for
cleanest output instead.

The second thing I'd do is take a hard look at the shielding of the
repeater. You *have* to have more cabinet to cabinet isolation
than the duplexer provides, or the duplexer can't do its job. That
includes the interconnect cabling too. It should all be double shielded
and *tight*. Make sure all the power wiring is bypassed too, IE use
feedthru capacitors to deliver power to the Rx and Tx boxes. That's
a good idea for the audio lines too.

One final thing, have you tried the repeater with a dummy load
instead of an antenna? VSWR on the antenna line can detune
the cavities and allow desense. You may need to do a better
job of matching the antenna line to the duplexer to prevent this.

2361. ProTek 506 MultiMeter Plus...

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-10 00:00:00 UTC
From: ku4qw@my-dejanews.com
Message-ID: <6t9eua$r3$1@nnrp1.dejanews.com>
Source record: 79266

I remember seeing a big thread about Multi-Meters sometime back, but wanted to toss this out. I have been looking at the Pro-Tek-506 on Circuit Specialists http://www.cir.com Homepage. They list it for $139 which if It does all that I think it does that seems like a good deal. They list it does...

10MHz Frequency Counter and AC Voltage (V) Dual-Display- The 3-3/4 digit, 4000 count meter provides an accurate digital readout of frequency and AC voltage in dual display mode. **(Does this mean I can mesure my VFO Frequency or is this just AC Voltage Freq?)

Capacitance and Inductance function- Tests capacitance to 100F and inductance to 100H **(Could I find out what all those old chokes and caps I have lying around are?)

I would like to hear from anyone that has one or knows about it and can tell me if it's a good meter. If this is not the one I should buy point in the right direction for a MultiMeter that does L/C at a Price near this one...

Thanks for any help...

Jim

Even brand-new Ge-transistors may seem 'leaky' compared to Si-types, but may usually work as they are supposed to. Ge-diodes measures 'leaky', but still I use a lot of them without any problems..... in detectors for measuring equipment - up to beyond 2GHz. I have re-used several old 1N34A and never experienced any difficulties apart from somewhat high capacity for VHF.

Until few years back we had much Siemens telegraph transmission (50Baud) equipment dated 1960-68 using Ge-transistors, still some part of this equipment is in use for telecommunications. 10 years ago I replaced electrolytic capacitors in 50 units, then they worked satisfactorily. Only in few cases I experienced any problems with Ge-transistors in this sort of equipment. It uses small-signal transistors and some smaller power transistors (less than 2W), believe the types are manufactured since late 50's.

Since the equipment performed well, I did not care to check for leakage

> balun is connected directly to the coils.

The point is that putting the choke on the input of the tuner doesn't
reduce the common mode currents that it is called upon to handle. It
is not seeing the differential 50 ohm impedance. However, with your
tuner, there is no other place to put it. Is your tuner in a metal box
tied to the coax shield? If so, that chassis is very likely RF hot.

You still have exactly the same problem. The choke is not seeing the differential 50 ohms so it cannot be designed for 50 ohms. However, it sounds like you have enough overkill built into it to handle whatever impedance it might be seeing.

What happens when one assumes that the choke is seeing 50 ohms is that one might decide that 300 ohms would be enough reactance or resistance for the choke to exhibit and that may not be enough because the common-mode impedance is unknown.

TS>the transmitter and a rf concepts pre amp on the reciever. I have a
TS>Sinclair CM-351 duplexor.

TS>Anyway, here is my question. Everytime I tune the transmitter to put out
TS>anything over 15 watts measured at the duplexor output, the rf seems to get
TS>back into the reciever and keep itself keyed and howeling etc...

TS>Under the 15 watts it works great.

TS>I'm sure you will need more info, but this is a start.

TS>Any ideas.

TS>FYI, I removed the pre amp, still had the problem, I tried a different tx
TS>amp, same problem.

TS>-Tim

It would seem that your tests have isolated the problem to the hamtronics
tx/exciter itself. Increasing the power out of the unit is changing the
operating conditions of one or more stages in that unit (probably it's
final amp stage). The potential for antenuating harmonic interference exists
with filtering; the most likely cause of the malady you describe is broad
band noise/hash in the final ouptut of the tx stage. I found on the VHF engr
repeater I built up about 25 yrs ago, that the grounding of the shield
covers on the varusus stages was not adequate and curred instability probs
that it had with copper braid soldered to the top of all the cans and bonded
to the chassis ground. Power Supply bypassing may also help.

A series question though. Why go beyond the 15 watt point. Even if you double
the output you would only pick up 3db..not a significant improment in trade
for a clean and trouble free operation.

Good luck.. 73,

Some laws are okay. Mainly the ones the Big Guy laid out for us... "Thou shall not steal...., thou shall not do murder...", etc. People need laws to restrain them only because they are irrational and as such, the strong would subjigate the weak and so you'd have the microcosm of what we have today: small governments bossing the weak around. With anarchy we fear our neigbor. With government we fear our police. Only the police have bigger guns and it would be harder for us to win a battle against them as they are supported by extorted funds en masse (taxes) and have almost unlimited resources.
Frankly, I'd rather live tribally, without the tax burdens. That's why man built BMG .50's and AK-47s.
We've created such a lovely, "civilized" society, haven't we? A society where the rich exploit the poor and the rich don't share the spoils of the rape of the earth with anyone but themselves. Strip away all our technology--our central air, our computers, our hot running water, our automobiles--and what do you have? Slavery. I'd rather go live on a subsistence farm in the 15th century in that case.
Rational people don't violate other people's rights. I maintain that laws are the result of the stupid, who ruined any remnant of freedom we had left, 200 years ago.

Source record: 79274

Well, from everyone's input I must conclude that my problem lies in the shielding itself. I used the A87 RF boxes provided by hamtronics, one for the TX and one for the rx. However, I used DB9's for the connections instead of feedthru caps. This may be the problem.

To test that the desense in the cabinet instead of coming through the antenna, is it reasonable to put a dummy load on the receiver port of the duplexor and a dummy load on the rx and check for the desense?

Anyway, as one pointed out, the difference in 15watts to about the 25watts that my setup will do isn't enough to rewire everything anyway. I just wanted to know the cause so I can keep from it next time...

Thanks

-Tim

This country was founded as a nation of laws. The reason for independence was because the King of England forced arbitrary and destructive taxes upon the people here to pay for excessive spending back in England ... sound familiar? In any case, this is not relevant to the discussion -- no civilized nation anywhere anytime can long survive when its people decide that selfish anarchy is the way to go ... you choose ... anarchy ALWAYS leads to tyrannical rule because people quickly discover that anarchy is horrible. Civilized people give a little to get a little, it is called sharing ... should have learned that pre-kindergarten.

Hi, Will

I cant answer all your questions, but I can tell you from experience
that wires in trees dont last more than a season unless they are
properly installed and probably using copper coated steel wire
(copperweld). Unless you are anchoring the 24 ga on a part of the tree
that is very stout, it will snap it in the first storm. Be sure to work
out a system of small pulleys and a weight or something similar so when
the tree moves, the line can play back and forth. I think you can do
fair when only one tree is involved, but I never had luck with 2 trees (
another degree of freedom in the system). I used to have a wire abt 250
ft from shack to a tree about 50 ft away , then about 200 ft to the
tallest tree on the ridge. The longest it ever stayed up was abt a yr. I
used 14 ga copper ant. wire, but should have used some copperweld.
You wont notice the effect of the insulation on wire at hf. Maybe the
length you end up with after tuning will be slightly different, but loss
will be unmeasurable. Also, as long as its copper or copper coated, you
wont notice too much difference from one type of wire to another. Again
the steel wire is stronger, but be sure its copper coated or it will be
lossy. I dont think losses get very bad on copper wire untill it gets
very small, like 26-30ga, but I cant remember the exact numbers. If
youre going with the random wire, the MOST important thing is to try to
make some kind of groung that works at rf and thats tough. Otherwise,
youll have a lot of loss and you might even have some rf floating around
the shack if you run much power. If you have good rich soil, some ground
rods will help, but the best would be a radial system or a tuned
counterpoise. On the latter, you have to tune one for each band and
switch in the correct one as well as tune you wire.
Oh, most near forgot, you do need some kind of insulation where the wire
is contacting the trees or youll be detuned and lossy when it rains. I
had mine suspended a short distance from pulleys using rope and a
porcelain insulator. I hope some of this will help. Again, make sure the
wire wont be snapped when the tree moves in the wind, insulate from the
tree and try to get as good a ground as you have patience for. Anything
ground is better than nothing.
Good luck
Don

Those auctions are real scams. I just looked at the one ZDnet is
promoting, apparently run by Egghead. They show required minimum bids
for some items equal to everyday retail prices I've seen. And then you
add an inflated shipping cost.

Caveat Emptor!

I think most people don't realize that many of the outrageous prices on Ebay are NOT real !!

So far eBay has made two changes: Several weeks ago which added a key to each bid form. With a little work, programmers were able to get around this. Now eBay is about to make a new change, which will randomly change security methods, making it almost impossible to write a snipe program. Now eBay says sniping is still allowed, but automated programs won't work anymore. Why disable automated programs? Because it allows "bid robots" to roam freely on eBay. What do they do? They bid insane amounts on thousands of items and hours... with no intention of paying, bumping out people who would. Sniping is the practice of waiting to submit your bid seconds before the auction closes making it impossible for anyone to place a bid after you.
As you can see, thousands of bids per hour are being made that are completely bogus!
If a bid is so outrageous that it doesn't seem real, it probably isn't!

Cecil's right. The choke balun chokes off *common mode* currents on
the outside of the coax shield. It doesn't even see the differential mode
currents. The differential impedance between inner and outer is irrelevant
to its function. It would be fair to say that a choke balun has no particular
characteristic impedance, so it doesn't matter what the tuner does.

What does matter is the common mode impedance at the point where the balun
is installed. That's what the choke reactance of the balun has to work against,
and that doesn't bear any fixed relationship to the differential mode impedance
seen by currents *inside* the coax. A tuner transforms the latter, but the former
depends on the topology of the entire transmission system.

Another thing that might be worth mentioning. Sometimes a particular length will be almost impossible to tune on a certain band with a given type of tuner. You can shorten or lenghten the wire some to find a happy compromise. I saw some data in either the handbook or antenna book that gave some lengths or equations or whatever to avoid certain problematic lengths. You might want to read or re-read that info.

Wait a minute. Cecil says (above) ".... putting the choke on the input
of the tuner doesn't reduce the common mode....

And you Gary say "The choke balun chokes off *common mode*
currents...."

For the sake of me I can't see where those two statements agree.

However, Let me restate my tuner situation again and I'll try to make
it clearer.

My tuner is a balanced tuner. That means the input AND the output are
balanced. It is configured some like a sideways U. There are two
adjustable coils. The coils are in series (One is series with on leg
of the transmission line and the other in series with the other side).
There is one adjustable shunt capacitor. The capacitor can be switched
from the input side to the output side depending upon the output
impedance required.

The tuner has a balanced input. Nether side of the input is connected
to ground. In other words there are two terminals for input just as
there are two terminals for output both sets are floating (not

grounded). Now, the balun is connected at the input terminals just as a balun would be connected to a dipole at the feed point. That is to say the common mode current doesn't even come into play because, for all practical purposes, it is choked off at the point were in connects to the input terminals (the coils) .

There is no difference between the operation of the balun in this manner than Cecil's point of attaching the balun at the proper point on a transmission line. Both are prevent common current in exactly the same manner.

The advantage of this set up is that when compared to a balun installed on the output of an unbalanced tuner is when my tuner is properly adjusted the balun sees an impedance of R50 with no reactance component which is exactly what it should see for optimum operation.

BTW: I'm going to be away for a few days so if this discussion continues I won't be responding after about 2100 hours this date.

.......snipped.............

Tim-- I built a 220 machine back in the 80's using the Hamtronics units. Great stuff for the price. However, I discovered that the shielding and bypassing they provided was insufficient to prevent desense under certain conditions.

I liberally sprinkled .01 caps on all control and B+ (boy, that dates me doesn't it!) lines and soldered heavy braid straps from everything to a common copper ground buss in the rack. Also, I used RG-214/U wherever I could inside the rack, transitioning to hardline at the back of the cabinet.

The bonding of everything in the system, I mean _ALL_ chassis, to a common, heavy copper buss that was in turn connected directly to a 16-ft ground rod seemed to be the mosty effective step in reducing desense and some spurs from the exciter/PA.

After a few months in place, we noticed some very strange noises, squeaks, and whistles on TX keydown. They were traced to a corroded joint in the steel fire tower, under which the machine sat. The joint was acting like a non-linear junction/detector. Cleaned it up and all was quiet.

A question, however, that another has raised: why raise the power? Only someone on a bad day at the very outer fringe of coverage would notice the increase in power.

I haven't had this happen to me (yet), but I know I've seen many items
re-listed a few days after the auction closed, with a note indicating
that the seller had been "stiffed", or the buyer never responded to
the seller's emails. Sounds like auto-sniping to me.

Actually, I've sold things on eBay for prices that astonished me, and I have yet to be stiffed by a buyer (at least on a high-$$$ item; I have been stiffed on a couple of nickle-n-dime items). However, you're right; there are plenty of items that close at totally unrealistic prices, and I'm certain that no one, even a rich dude with lots of money, would bid that high.

> an item on ebay where the successful bidder could not be identified?

Nope. I've got several items on ebay right now that seem pretty normal prices. The Heath amp is a little low and Philmore chrome mono tube preamp seems a little high... But it is NOS unused in it's original box w/ paper work and parts bag.... - the S&G safe lock seems a bit light - but I figure there's just not that much demand for that kind of high secruity lock... The plasitic model submarine kit at $52.00 is just about right - I paid $40 ea. from a dealer for two of them about a year ago - so like I said - that seems about right... The Mini Pops rhythm unit who knows??? I'll be happy where ever that ends up (came on the Hammond A100 I bought a few months back - on ebay - which was super low!!! (you can't hardly touch a Hammond B3/C3/A100 class organ around here for under $3500 - and nice ones reach $6000 -- I bought a _really_ sweet A100 in great shape for $1500 - on ebay... The bid robots must have been asleep! (as were about a zillion others looking for a good deal on tonewheels!). Old multimeter at $1 is maybe a tad low - I've sold some pretty pricey stuff on ebay - never had a problem with the high bidder...

best regards...

Unlike other auctions E-Bay only offers items for sale by
individuals and then they get a percentage of the selling price.
E-Bay sells nothing itself. Those high prices on E-Bay are the result
of _Human Nature_, people let their ego's get out of hand and then pay
ridiculous prices just to win the bid. I always buy items via
pricewatch www.pricewatch.com or off the misc.forsale newsgroups and
then sell via E-Bay.

Hi John OM,
You have to remember, ebay is not in the 'real' world, it is just the
SF Bay Area, HI! Too bad there is not an 'ebay' in some other part of
the country where prices paid for things are much lower.

The balun is a beaded choke, right? The 50 ohm differential voltages
and currents are inside the coax and the beads are on the outside so
the beads do not see 50 ohms. Without the beads, the current tries
to flow back down the outside of the braid and since the coax is
short, it tends to see almost a dead short. The beads insert a
high series impedance which makes the current take the path of
least resistance. Again, if the differential currents are balanced
the choke sees no impedance at all.

Danny, the 50 ohm voltage and current is inside the coax. The beads are on the outside of the coax. How in the world are those beads going to see what's inside the coax?

Answer: they aren't. You need to measure the braid voltage and current without the choke to find out what the impedance is (if you really want to know). I would bet $20 that it isn't 50 ohms. If the coax is very short, I would bet the outside braid impedance is very low without the beads.

I bid just under regular retail for an Edison Cygnet
Horn, only to find it relisted the next day saying that the
top bidder withdrew. I wrote immediately and agreed on a
price with the lister, for almost the highest amount, and
sent my check immediately. He held it 3 weeks and returned
the check, saying that the top bidder had decided to buy.
Right. He just found another buyer who paid more than he
had agreed to sell it to me for.

What was the rest of the sentence? Putting the choke on the input
of the tuner doesn't reduce the common mode currents that the choke
is called upon to deal with. Roy's paper proves that. I didn't say
the choke doesn't reduce common mode currents - of course it does -
that's what chokes do. But the choke has to deal with approximately
the same common mode currents whether on the input or output of
an unbalanced tuner.

> For the sake of me I can't see where those two statements agree.

If you hadn't chopped off the rest of my sentence, it would be
readily apparent.

> There is no difference between the operation of the balun in this

That's true but neither see the differential currents which is where
the 50 ohms comes from.

Repeat after me (us): The balun DOES NOT see the differential currents
and therefore doesn't see 50 ohms except by accident. If the differential
voltages and currents are perfectly balanced it sees absolutely nothing.

IMHP - it's what the traffic will bear. Some prices are very high but there always seem to be buyers willing to pay. Some prices are reasonable, like the scanner and receiver I just auctioned off. I got several bids for each but not more than I really thought the items were worth if I were the bidder. On the other hand, I bid on a scanner and was outbid by about double. I didn't think it was worth what soemone finally paid, but who's to say. I eventually bought that item at RS for even less then I was going to pay if I had been the high bidder. Go figure!
It's fun to "shop" Ebay and see what's going for what price. And you never know, your bid may be the high one.

Repeat after me the balun works best when operated within its design
parameters.

The whole start of this was the statement you made that a 4:1 balun
doesn't work well under large reactive impedances. To which I stated
that no balun works well under those conditions (ie.. 4:1, 1:1 or
X:1).

I submitted that the system I use is much more effective than placing a balun on the output of an unbalanced tuner.

If a balun is operated outside its design parameters then the operation will suffer.

A balun designed for a 50 ohm load impedance works best at the designed load (R50 +J0). Likewise a balun designed for a 200 ohm load works best at that load (R200 +J0). When you vary away from the designed specs (as will happen when using a open-line feeders on a multi-band antenna) things get distorted. The system I use does away with that problem. The balun is operating exactly as it was designed to because the load presented is exactly what it is supposed to be. It really is better, no make that much better, that hanging a balun on the output of an unbalanced tuner.

Now that I think about it, it shouldn't matter if I use a current or a voltage balun in my application as the load is 1) balanced and 2) at the designed load impedance for the balun.

Danny

2401. Inverter +12/+150V 50mA

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-11 00:00:00 UTC
From: LA8AK@online.no
Message-ID: <35f99f33.5783204@news.online.no>

Hi
I wish to operate a 65 year old vintage 2W AM/CW 3-6MHz radio transceiver from my car and need to build an inverter. I got a PYE Cambdridge inverter transformer (1.5-3kHz?), problem is that the output voltage is 300V with 2x12V input.

If I connect the primary windings in series, the output voltage may be halved. The suggested circuit is shown below (dos.txt). Is it particular problem using such totempole driver? (one transistor not switched off when the other conducts).... I hope my driver will manage this. I need somewhat over 16V to switch the upper transistor into saturation (24V rectifier).
Is it a bad idea to take 1.5A 6V from the primary winding(10W)?
The original transformer is supposed to deliver +300V 100mA to some QQE03/12 and QQE03/20 valves.

Inverter for Telefunken Torn Fu.b1 mobile radio.

```
|------------------|-----i/p----< +12V
| to +24V |
D Q2 rectifier 100uF
----G IRF | |
S 630 | Tr.1 |--- +6V 1.5A o/p
|-----|--primary---|
D secondary |
----G Q1 100uF
G IRF630 |
-------|------------------|--------<Chassis-Gnd
```

driver and secondary circuit not shown
O/P 1: +130-150V 50mA to +125V anode voltage regulator
O/P 2: +6V 1.5A to +2.2V filament voltage regulator

Yes, in my case I am using a bead current type balun, but I could have
well as used a coaxial, iron core, or ferrite core balun. The beads
were handy and easy to use so I used them.

If I were to adjust the tuner to present a high reactive impedance
load to a balun designed for a 50 ohm load, say.... R50 + J2,000 or
greater, then you can bet the farm there will be substantial common
mode current. And, more importantly, an unbalance output from the
tuner. Why because the balun is being operated outside of its design
parameters.

In you example above the differential currents are maintained BECAUSE
the balun is doing it job. It can only optimally do it job when it is
operated within its designed parameters.

I'll be you a beer of your choice that my system using a balun
connected to a balanced tuned network which in turn is connected to a
open line does a better job across the bands that an unbalanced tuner
connected to a balun (of any ratio) on the output side of the tuner.
Because as you go across the bands there will be points were the
balun is operating outside of its parameters and not doing the job for
which it is intended.

The only thing I refuse to drive to TX to deliver, but on the other hand I won't have to..... Hi

Danny

2403. FS: 2000 count quad encoder

Newsgroup: rec.radio.amateur.homebrew

Since you only need low power you have the opportunity to make a very nice regulated high voltage supply. Use a regulator to reduce the 12v down to whatever you need for the desired output voltage, use the output of the invertor (reduced by a potential divider) for the feedback voltage to the regulator. Since the invertor is now inside the feedback loop all those lousy load characteristics are eliminated and you have a nice stable output voltage - just right for a good tone on an old tube tx.

A 723 would do the job very well. Used to work on prof video displays that used just this set up for generating stabilized EHT.

And Danny, inducted RF on the ladder-line can cause exactly that
high impedance condition.

> In you example above the differential currents are maintained BECAUSE
> the balun is doing it job.

You are ignoring inducted RF on the ladder-line. You are only considering
"leaking" differential currents which is only *one* source of common-mode
currents.

> I'll be you a beer of your choice that my system using a balun
> connected to a balanced tuned network which in turn is connected to a

The point is that neither you nor I know how good a job the balun is
doing Vs how well your antenna system is balanced. How do you know
exactly how much inducted RF is on the ladder-line? I would be a fool
to take such a bet with so many unknowns. Inducted RF on the ladder-line
can cause all sorts of problems including false readings on an SWR meter.

I'm not criticizing your configuration, just pointing out that it may
not be as cut and dried as you think. Gary once taught me a lesson
about inducted common-mode currents.

>ebay are outrageous?

I think (1) there are a lot of collectors hoarding things they can't really use, expecting a stock market crash on 1-1-Y2k and wanting swappables; (2) a lot of con merchants are pretending that beer mats are valuable; (3) a lot of people finally convince their insurers by auctioning a valuable back to themselves; but they have to place an outrageous Reserve in order to do that without any risk of selling.

All of this makes for many outrageous prices not only on eBay.

Cecil,

I fail to see - as far a the balun is concerned - any difference from
using a tuner such as mine or the transmission line as you do. 50 ohms
is 50 ohms and that is what the balun is seeing - providing the tuner
or feed line is adjusted properly.

Why? If the tuner is adjusted properly why not? Are you saying that
the tuner can not be adjusted to present a 50 load input impedance to
the balun? If that is true I might as well throw away my copy of
"Reflections".

>However, with your
>tuner, there is no other place to put it. Is your tuner in a metal box

Nope, On the inside of the tuner the where the coax connects to the
SO-239 I use a shield to keep the current on the inside of the braid
connector junction. Unless the theory of skin effect is violated there
is no noticeable common mode current. The chassis is not hot.

Hi John!
If your computer specs specified that it can be powered from a car 12 volts system you should know that such a system provide in reality 14.2 volts dc when the engine is running, so you now only need to drop you battery pack .8 volts so a good diode will do the job. And if you want to use a three pin voltage regulator don't forget that there is about 2 or 3 volts absorbed by the regulator himself between the input and output so the 15 volts source will become 3 volts down say 12 v. when the battery is fully charged.
Good luck !

Danny, you just broached a most interesting question - the question of whether it should make any difference whatsoever whether it's a voltage balun or a current balun. Of course, I am questioning only in the context of transformer baluns - not ferrite beads. And, of course, I assume, as you say, that it would be working into its correct load impedance.

One thing that has bothered me for a long time is this question of whether or not a proper transformer type balun, installed at the antenna center, really does its job by eliminating the problem or by blocking the common mode RF. I see it as two different mechanisms.

Ok, repeat after *me*, there is no particular design value for differential mode impedance presented to a choke balun. It doesn't see that impedance. The only impedance the choke balun sees is the longitudinal common mode impedance. It doesn't care what the differential mode impedance is. With a "floating" tuner, the common mode impedance is the same on its input as its output, so it doesn't matter at which end of the tuner you place the balun.

(This isn't true for a grounded tuner. And of course it should be obvious that you need a balanced tuner topology on the balanced line side and an unbalanced tuner topology on the unbalanced side when you're transitioning from coax to ladder line. That's a separate issue.)

>The whole start of this was the statement you made that a 4:1 balun
>doesn't work well under large reactive impedances. To which I stated
>that no balun works well under those conditions (ie.. 4:1, 1:1 or
>X:1).

Ah, but a *voltage* balun *does* have a design impedance for the differential mode currents. It *does* matter what the differential mode impedance is when using a transformer balun. And that's the difference. Operation of a voltage balun will be adversely affected by being operated at a differential mode impedance far from its design value. The choke balun is insensitive to the differential mode impedance because it doesn't see it.

> I submitted that the system I use is much more effective than placing
>a balun on the output of an unbalanced tuner.

I see no reason to believe that's the case.

>If a balun is operated outside its design parameters then the
>operation will suffer.

But a choke balun has no design parameter that is dependent on differential mode impedance.

>A balun designed for a 50 ohm load impedance works best at the
>designed load (R50 +J0). Likewise a balun designed for a 200 ohm load
>works best at that load (R200 +J0). When you vary away from the
>designed specs (as will happen when using a open-line feeders on a
>multi-band antenna) things get distorted. The system I use does away
>with that problem. The balun is operating exactly as it was designed
>to because the load presented is exactly what it is supposed to be. It
>really is better, no make that much better, that hanging a balun on
>the output of an unbalanced tuner.

That would make sense if the differential mode impedance mattered
to the balun you are using. But it doesn't.

>Now that I think about it, it shouldn't matter if I use a current or a
>voltage balun in my application as the load is 1) balanced and 2) at
>the designed load impedance for the balun.

If you were using a voltage balun, that would be true. A voltage
balun does have a particular design differential mode impedance,
and operating it away from that impedance will have undesirable
results. That is not true for a choke balun.

>whether or not a proper transformer type balun, installed at the
>antenna center, really does its job by eliminating the problem or by
>blocking the common mode RF. I see it as two different mechanisms.

Lets look at this in more detail. A choke balun is just a bifilar choke. The choke is in both legs of the circuit because it is designed to only present an impedance to common mode currents. The differential mode currents aren't affected because they generate no net reactance in the choke (the differential currents are equal and in opposite directions through the choke so net reactance is zero). Therefore it doesn't matter to the choke what differential impedance they represent. The choke reactance is only visible to currents that are unbalanced, and impedes them. These are the common mode currents the choke balun is designed to suppress. The choke must have a high reactance with respect to the *common mode* impedance it faces. It should be obvious that a choke balun can only be a 1:1 device with respect to differential currents, but it doesn't care what those differential impedances are.

A voltage balun is a more conventional transformer (typically wound to be an autotransformer). It can have ratios for the input and output differential impedances of other than 1:1. Its self-reactance must be large with respect to the design differential impedance, just as any transformer winding must be, or its efficiency as a transformer plummets. So it is sensitive to the differential mode impedances of the circuit in which it is used.

Now a choke balun has the effect of enforcing equal currents into the two legs of its load (assume a dipole). This is because the differential mode currents in a coax are equal and opposite in direction (Kirchhoff's law), and since the choke balun suppresses common mode currents,

those differential currents are the only currents allowed to flow into the load.

A voltage balun has the effect of presenting equal voltages (180 degree phased) to the two legs of the dipole because it is a transformer winding. Now if and only if the two legs of the dipole are equal in impedance, will there be equal currents flowing in the dipole legs. So a voltage balun does not *force* current balance as the choke balun does. It only *permits* balance if the load is truly balanced in the first place. Most real dipoles aren't truly balanced because of environmental factors. So in general, a voltage balun won't effectively suppress common mode currents. Since that's the main job we want a balun to do, transformer baluns aren't good baluns.

They *may* be good transformers if their self-reactance is high with respect to the differential mode impedances presented to them. So we should consider the voltage balun to be primarily an impedance transformer rather than a balun. The degree of balance that it may enforce is totally dependent on load balance. A choke balun is not a differential mode impedance transformer, but it is a good balun because it forces current balance regardless of the balance of the load.

Aren't ALL auctions? The whole concept is a bunch of people competing
to see who can pay the MOST for an item. It would be silly to expect a
LOW price from an auction.

For some folks, Ebay prices are a bargain and
a chance to find sets they may otherwise never
run across. There are some isolated areas where
one doesn't have the opportunity to attend shows or
auctions to find this stuff. I have found a few radios
(well, one anyways) that I had been searching for,
and got it at the going market rate.

The trick is to set a price in your mind, bid it,
stick to it, and hope for the best.

Pete

SF Bay Area ??? are you Trolling ??? E-Bay has listings from
individuals all over the US and other parts of the world, they've
also just been named to officially take over AOL's classified
ads/buying/selling. As I mentioned earlier E-Bay _Doesn't_ sell
anything _Themselves_ , and they _DON'T_ set the prices, they merely
get a brokerage or percentage of the item's worth when it's sold as do
most _true_ auctioneers. I suspect it's folks ego's that cause such
high prices to be paid but you sure can't blame E-Bay for folks that
bid _more_ for items than you can buy them new for.

> the designed load impedance for the balun.

It's interesting to compare a 1:1 current balun made with a bifilar winding on a core, and a voltage balun made by adding a third (tertiary) winding to the current balun. Using the voltage balun, if the load is perfectly balanced (meaning, in this case, that the impedances looking toward the load from each of the output legs of the balun to the "cold" side of the input are equal), there will be no current in the third winding. That being the case, it makes absolutely no difference whether the third winding is there or not; it can be connected or disconnected with no effect. In this case (only), there's no difference in operation between a current a voltage balun. But if the impedances seen by the two output conductors aren't exactly equal, there is a current in the third winding of the voltage balun. This current, it turns out, becomes a common-mode current on the feedline. By simple Ohm's Law, in order to keep the voltages on the two legs equal, the currents must be unequal if the impedances aren't the same. This is the common-mode current. (Numerically, the common-mode current is actually 1/2 the difference.)

So Danny is correct that it makes no difference which kind of balun he uses if the load is balanced. You can also cut the winding on a voltage balun without making any difference if the load is balanced. However, I don't believe that the impedance to ground is the same from the two input terminals of the balanced tuner. If they were, you'd burn yourself off the coax shield at the tuner input.

The issue of "designed load impedance" has been addressed by others, and I agree with what the other posters have said.

Yeah, but be sure to use a jumper wire of the same length as the coax
between the two ports. Breaking that ground loop may make your
leakage problems seem to go away, but they'll be back when you
hook the coax back up.

>Anyway, as one pointed out, the difference in 15watts to about the 25watts

Receiver desense almost always hurts your coverage more than reduced
transmit power.

Danny, you just broached a most interesting question - the question of whether it should make any difference whatsoever whether it's a voltage balun or a current balun. Of course, I am questioning only in the context of transformer baluns - not ferrite beads. And, of course, I assume, as you say, that it would be working into its correct load impedance.

One thing that has bothered me for a long time is this question of whether or not a proper transformer type balun, installed at the antenna center, really does its job by eliminating the problem or by blocking the common mode RF. I see it as two different mechanisms.

How do they get around the registration part in order to bid? I just got burned on a telephone to the tune of $25.00. I was high bidder and sent my money order but never received the phone. E-bay had no valid address and the phone was disconnected. I have also been burned on other items..I bought a computer with 17" monitor and the monitor crapped out after two days. The seller said I must have changed something and would not make good. I have had others, but those were the worst. I would say 70% good and 30% bad. I have bought items very cheap and sold items very high (much to my suprise) so I guess it is a crap shoot. A lot of people actually run their businesses on E-bay. I wish there was a way to tell who is a private party selling an item and who is a business. I think that makes a difference.

Others have explained it so let me just say that if the antenna is
unbalanced, e.g. the two legs of a dipole have differing impedances,
a voltage balun will guarantee common-mode currents because a voltage
balun guarantees equal voltages which will guarantee unequal currents.

Also, without fine tuning, there is probably no such thing as a
balanced dipole in ordinary terrestrial ham environments. OCF
dipoles are unbalanced on purpose.

Could someone please tell me where to take the audio in and out from an
FT-990 radio.
There are plugs for packet and what not (friends radio) but where would be
good to plug in on the back to get the audio to send and receive SSTV??
Any info would be appreciated. Oh and I looked in the owners manual and it
doesn't say anything about SSTV. DARN.
Thanks all.

Yeah
We have this problem in OZ. The lowest pager frequency here is on 148.012
MHz
I suspect your first problem is the receiver mixer which is not up to
handling the power levels from these pagers (up to 1.2 KW EIRP in
Australia). Assuming you dont want to modify your receiver then helical
filters may offer some improvement (try Cirkit in the UK) They are much
smaller and cheaper than cavities. I have built a preamp using the CF739
Gasfet and two 2 section filters. On the spec an the response rolls off
about 15-20 dB at 2 MHz

Try using a 1/4 wave tuned stub first. it's cheaper.

Even though that seems like a lot of loss, I'd still recommend *starting*
with the tuned stub. He can always upgrade later, after he proves the
intermod will go away by filtering. If he's just using it to access the
local repeater(s), the loss may be acceptable if it allows him to use the
repeater(s) without having to listen to the intermod too. Actually, the
first thing I would have done is to make sure that the antenna didn't have
any loose/cold solder joints which might *cause* the intermod to begin with.
I'm assuming he did too.

If every idiot like you decided to go transmitting where they want,
without a licence, and without knowledge on harmonic
radiation/interference from your homemade spur generator then you would
probably complain when an aircraft comes down on your house while you
are at work, killing all your family!
Get the picture now? that's why licences are issued and standards are
met!

Don, there IS a place.

It is kind of strange but the BOB DUCKWORTH's APACHE AUCTION SITE
has sold a number of things at VERY VERY low prices.

I have found it is a great place to unload stuff I don't need and give someone
a bargain at the same time. There is NO FEE there!

eBAY is getting rich off the sales of things at highly inflated prices. Their
comminssions are huge for something that doesn't cost them much to operate.

Try the DUCKWORTH-APACHE auction site next time!

Go to -
http://www.atl.org/wits/

and then click on Auction.

Some of the cattegories have bizarre sounding names, but I have found some great
deals on radio gear and computer items there! ALso sold a few bits and pieces.

It is nowhere near as big as eBay, but it is FREE!

Recommend you consider a PAR Electronics or other filter.

A 1/4 wave tuned stub is too broad. You will get about 12 dB
loss on 2 meters if you make an RG58/U stub tuned 10 MHz up the band.

I built 1/4 wave coax stub filters and measured their
losses using a modern HP spectrum analyzer and tracking generator.
Did the same for two PAR filters.

For more info, see my column and frequency response graphs
in July 1998 Monitoring Times magazine.

What that is telling you is don't use that lossy stuff on VHF. Try making
the stub out of low loss coax like CATV hardline. That'll have a higher
Q, and a narrower and deeper notch. Still free too.

2468. Diamond X500HNA Antenna

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-13 00:00:00 UTC
From: Carl Domanico <cmd-dell@worldnet.att.net>
Message-ID: <35FBDEA5.316C4957@worldnet.att.net>
Source record: 79215

Hi I wonder if there is someone out there who is very familiar with the Diamond X-500HNA Dual Band 144 / 440 Vertical Antenna.?? Recently, I purchased one and installed it on the roofï¿½. Anyone familiar with this type of design Antenna knows that there are no user adjustmentsï¿½.you just put the sections together attach your coax and your radioï¿½.I initially was using an older comet 144 / 440 a CA-2X4Zï¿½.it worked fine for about 8 yearsï¿½then I found it developed a problem with the S0-239 connector at the baseï¿½it seemed to have literally fell apartï¿½but as for the Antenna weï¿½ll it worked great for 8 yearsï¿½.great signal and great matchï¿½.Anyway I decided to go out and put up a new Antennaï¿½so I sprung for a big $ 240 for this Diamondï¿½a bit heavy in construction and it has an N connector at the basses even sprung for this LMR-400 Times-Microwave coax cableï¿½Weï¿½ll after the antenna was erected and this great cable was installedï¿½I proceeded to make an swr graph on both bands from one end to the otherï¿½.Weï¿½ll after checking 440 MHz..I was pleased..since the swrdid not exceed 1.5 from one end to the otherï¿½However, on two meters it was a horse of another colorï¿½It seemed that the bandwidth started a bit higher than it should haveï¿½down on 144 MHz I was getting 2.0. as I moved up the band it seemed to start to dropï¿½at 145 MHz..it was 1.6 ï¿½and then as I moved up further it came to a more normal readingï¿½I even went past 148 MHz and found it to be goodï¿½.Bottom line is the antenna was tuned to kick off a bit high than it shouldï¿½I called Diamond and they were very nice about it..They said I could send it back to them to have the Antenna Re-tunedï¿½Now this is all well and good but that means I would have to take it down..package it up..ship it to the West Coast from New Yorkï¿½pays shippingï¿½And then when I receive it back put it back up and hope it is correctly tuned.. There are no user adjustmentsï¿½and even if there were you have to be carefull that you donï¿½t knock the other Band out of wack..while trying to adjust oneï¿½What I need to know from someone who is very technically familiar with this antennaï¿½Is there a way I can Make an adjustment on it to bring the SWR back to where it is below 1.5 from 144 MHz..To ï¿½148 MHzï¿½.The Technical Design is 5 / 8 wave three- element C-Load antenna (2 Meters) and 5 / 8 wave eight-element C-Load antenna (70 cm).. I have various test gear..a Bird Wattmeterï¿½High End Digital VOMSï¿½a couple of SWR Metersï¿½and some good common senseï¿½.If anyone out there in the Radio field can help me out here I would be indebted foreverï¿½..

Thank You Very Muchï¿½.Carl M. Domanico N2MFW

Cross-posted to: alt.ham-radio.hf,alt.ham-radio.morse,alt.ham-radio.ssb,rec.radio.amateur.antenna,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.misc

I'm a Tech - Plus and have been banging out contacts on the novice portions of the 15, 40, and 80 meter bands. My code speed has increased dramatically since deciding to get on the HF bands doing code instead of hopelessly practicing with audio tapes until reaching 13 wpm and then never going back to CW once upgrading (that's what many of our fellow hams do). For all you old timers out there who love their code and feel it should stay, well I agree. I was wondering why virtually all the special event's do not include the novice portions of the HF Bands in their Communications Plans. I'm beginning to think that the Ham community (deliberate or not) excludes the novice operator from special events when actually they should be providing the new guy every opportunity to participate. Setting up on a Novice Freq is not a whole lot of effort, but would reap much benefit. Especially when considering that our lower ranks are dwindling and techs are never going past 5wpm.
The FCC with the ARRL are considering major changes to the CW requirements and has created an explosion of debate. I think the ARRL is doing the right thing. Ham Radio is dying a slow death. Perhaps all Hams should ask themselves what they've NOT DONE to help the new guy thereby forcing the ARRL to take drastic measures to save the Hobby. Does the word SPECIAL in "Special Event" mean "Novice need not show up" ?

hmmmmmmmmmmmmmmmmmmmm

Howdy Fred....Use a diode switch to do this electronically...and simply - This is how many 2 meter rigs adjust for +5kHz offsets etc and HF rigs adjust for a slight RX offset....the amount of voltage you apply to forward bias this diode switch can be trimmed with a small pot to put your offset amount to what you want. Suggested reading in the Radio Amateur's Handbook every issue from 80's up.
73 - Keep on tinkering...THAT...is REAL HAM RADIO!

2473. Skytel SkyWriter Pager mods ?

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-13 00:00:00 UTC
From: RHS Linux User <aaa@bbb.ccc>
Message-ID: <35FC1B61.49362CB2@bbb.ccc>
Source record: 79220
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.misc,rec.ham-radio.packet,rec.radio.amateur.packet

The skytel skywriter 2000 pager is a nice little unit which runs it's own OS and allows developers
to create apps to run on it. It includes a small multi-line display and fairly usable small keyboard all
in a compact unit. While attending an IETF conference recently Motorola loaned attendees these
units for the week and I had a chance to try one.

I was wondering if anyone else had thought about or looked into modifying these units to work with
packet? Seems llike the perfect little unit! The units can be purchased for around $300 and if they could
be modified to operate on Ham frequencies surely software could be written to handle packet.. From there
I can think of all sorts of interesting apps such as display of simple APRS maps, DX cluster alerts with
greater urgency if the region of the world you were interested in started showing up a lot, perhaps even contest logging. How about
sending quick notes directly between two units while at a Ham Fest.

I was curious about this pager generally so I have sent for a free developers kit (also part of the conference promotion) This will give me
software answers. Anyone willing to try to open one up to see about the frequency issues?

From: n/a
Message-ID: <35fd1f8b.9312340@news.atl.mindspring.com>
Source record: 79223

Hi all I am looking for specific design info so as to be able to
calculate the correct cap and inductor values for a clapp based
oscillator for use in the vhf region. I have scoured many books
looking for this info but no luck yet. Found plenty of examples though
but very little theory.

Also need to know how to choose the feedback cap values
so that maximumn amplitude can be obtained from the active device
such as a n ch fet or bipolar transistor.

If any of you can help me it would be very much appreciated.

Best Regards....Paul

I had good success using halfwave tuned coaxcable filters from heliax
LDF5-50 cable, a series tuning capacitor tunes out the inductive effect.
I made several different filters in the range 100-500MHz. The notch
width may be very narrow, a two stage filter was made to improve some
15dB on 600kHz duplex distance 2m repeaters.

Need to move these items.
1. NIC (new in can) 3CX350A/8321 and 4CX350A which have the
same specifications. One a triode and one is a tetrode. Priced at $120.00
ea. or make a reasonable offer.
2. 2 ea 4CX5000A/8170 @ $400 and $600 Both used pulls.offers accepted
also.
These were in Colllins transmitters for the Univ of Hawaii, and were
used for daily
ops for about 15 min per day. The spare transmitter was only tested
once a quarter
so they do not have much time on them.
3. 8965 Planar Triode $20 in AES now $8
4. 6816 Planar Triode $40 ea. listed at $70
5. 6081 Klystron, I think, as it has a waveguide output flange. Made by
Omni-wave
6. 6442 GE UHF amplifier tube, pull from UHF power amp spare (unused)
$40 in
AES. now $20
7. 7554 GE UHF amplifier, preamp driver tube also listed at $40. now
$20 each.
8. From same power amp, have 4X150A/7034 Eimac tube. $40 in AES,
now $20
===== also have an unopened 3X2500A Glass seal not ceramix (3CX) Owner
wants $400

All above tubes areVarian/Eimac unless otherwise identified.

I recently got a communications specialists 64 something controlller, for a 220 mhz radio I have had for almost 15 years.

Needless to say, I blew the thing, but I wonder how it works. There is a voltage regulator, which also starts:

A microcomputer, MC???????? which does the actual work.

I'm just curious as to how these beasts work. That company has dropped their really small board with the ceramic resonator, and replaced it with this postage stamp board (can't complain about the size), which however doesn't fit..

We old folks with Alzheimers have trouble with all this new stuff. I suspect that the CPU does the whole job.

Hi Paul;

Try the book: "Design of Crystal and other harmonic oscillators" by Benjamin Parzin, copyright 1983, John Wiley and Sons.

A very good book with an algorithmic approach to design of oscillators.

I would have sent this message to you directly, but your anonymous signature would not allow that.

John...

I agree. Almost all the dealers that sell their radios on Ebay fully expect retail or higher. Although I have purchased radios from Ebay. I limit my participation due to the very high prices. I mainly go for the stuff others are not interested in.

But clearly the dealers want NO LESS than retail, and are happy to get far above that. But in the final outcome it is us, the buyers, that cause this problem. No seller is forcing us to purchase their goods.

SO bid responsibly, and LET THE ITEM GO IF IT IS TOO HIGH. If we the buyers start to get this discipline, prices with retreat!!!

That's "my opinion on the subject..

Mark:

I don't think the 202,203, etc., are manufactured anymore. You can find
them
occassionally from some mail order surplus houses though. You might
check out Teltone's M-8870 DTMF receiver. Same deal with slightly
different pin-out (actually I've used 'em both and think the 8870
out performs the 202 chip). The Teltone stuff was available from
Digikey (www.digikey.com) some time ago. If not, there are other
manufacturers of similar DTMF chips.

You will have to do a whole bunch of work. The Pagewriter 2000 is
hardcoded to work with a ReFLEX50 or ReFLEX25 network. The Protocol
stack is hardcoded in masked microcontrollers. The RF transceiver
operates at 900 MHz, and will not translate down to 144 or 440 MHz
withoug extensive redesign. Have fun with the software developers kit,
there is a bunch of neat software that you can do on this.

Hi,
I don't really agree with what your saying, but I liked your "home-made spur generator" remark, I'll have to remember that!!
I think a lot of the problem with interference is the quality of some kits (not wanting to start an arguement and name names). Fm broadcast isn't rocket science, but often kits are sold with little or no information for the inexperienced home builder to avoid such problems. More discussion of the problem on newsgroups such as this is a good way to educate people about how to avoid such things, not rely on licensing. My experience of licensed operators has been that THEY often cause interfernce, especially commercial radio stations.
The other thing is this bizo about planes falling down on peoples heads because of interference (presumably on second harmonics or the suchlike). Modern areoplanes are now equipped with windows and human pilots, while interference from a 1 watt TX might help an accident happen, I'd be very surprised if it did. Now blasting over an ambulance frequency (as some genius did here not so long ago) during a dash to hospital would be a problem; but whats this fascination with areoplanes??

Regards,

Sean

2491. AM synchronous demod question

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-14 00:00:00 UTC
From: "Clifton T. Sharp Jr." <agent150@spambusters.ml.org>
Message-ID: <35FCC41C.58E3@spambusters.ml.org>
Source record: 79097

All the synchronous AM demodulator circuits I can find seem to rely on
a good strong input signal, so they can overamplify and limit the IF
signal to generate the unmodulated in-phase carrier. The PLL comes to
mind, but Kiwa (who no longer makes a sync demodulator) says:

The PLL or phase locked loop types can be particularly troublesome
when the carrier signal is noise modulated. It may at times lose lock
creating a howl and a Donald Duck voice to the audio.

That's all the clues I have. I'd appreciate ideas (though my book budget
is spent through April 13, 2212 and the local libraries suck).

I'll be interested in hearing the other answers to your question. I have a little Sony SW receiver which has synchronous AM demod as a switchable option, and it does quite well on marginal signals. No idea how they do it.

>

The pick-up and rectification of a signal is rarely flat, so even
with a perfect, zero AM component at the transmitter, the overloaded
equipment or the path can convert FM to a small AM component which
becomes audible.

Cheers
David

Hi.

I have the S11, S32, S12 & S22 parameters for a couple of SMD GasFets i have (XMFP1-M3 & XMFP4-M3 ... 100mw/3watt at 1.8ghz resp'), i also have a smith-chart.

I need to match the gasfets gates/drains to 50R. Can anyone point me in a direction where i can find details on how to use these parameters to work-out the capacitor & stripline inductor values (using the smith-chart i guess).

The data sheets do have various circuits/PCB designs for 900MHz & 1.8GHz but i'm going to be using them at 1.2GHz to 1.3GHz ... typical

All help gratefully received.

Thank you ... Clive

Hello, Sean--

Two aspects cause concern: instrument landings (IIRC, the glide-slope localizer frequencies are just above 108MHz), and communications (aircraft use amplitude modulation). A pilot dealing with an in-flight emergency or an instrument landing in bad weather doesn't need communications problems.

Also, consider that RF leakage from poorly-maintained cable TV systems can affect the aircraft bands and raise the background RF noise level. Add an off-frequency broadcaster or a spurious frequency radiated by ANY transmitter, and a pilot in difficulty could get into real trouble aggravated by poor communications.

Radio Shack used to sell the SSI202 on the 'blue wall'. I still have a couple down in the junk stuff somewhere. But they went in really tight supply when magazines like 2600 published construction articles a couple years back on tying one right to your LPT port on a laptop to monitor tones.

I'm recently divoced, and all my stuff is still in junk boxes in the garage. If I even get them unpacked........

I don't know if it's still available in their National Parts, but maybe through their RSU.

2500. Announcing West Coast Triple CW Event

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-14 00:00:00 UTC
From: Casey Bahr <caseyX.bahrY@intel.com>
Message-ID: <35FD386A.5534@intel.com>
Source record: 79106

OM, XYLs, YLs, especially FISTS members,

Sorry for the "spam", but I'd like to tell you all about
an upcoming special CW/code event on Saturday, September 19th!
Seems that the September FISTS Keynote newsletter that contains
our full announcement is going to be too late for the event,
thus we're trying to spread the word as best we can by other means.

From 2000Z on the 19th until 0400Z on the 20th, three
FISTS-affiliated clubs, K7FFF, K6FFF, and WA7YYY are hosting
a special CW event on most bands, including Novice segments.
The name of the event is the West Coast Triple, named for the
callsigns, three club states (OR, CA, WA) and the points awarded.

For current and future FISTS members each club contact is worth
3 points towards FISTS awards (9 points total!) and if you work
all three clubs (any band) and submit an SASE you can receive
our special WCT Certficate, suitable for framing.

All the details can be found on the K7FFF website, specifically
at: http://www.imagina.com/webpages/casey/k7fff/FNW_WCT.html

We really hope to hear and work all of you who choose to participate!

Now back to your regularly scheduled newsgroup...

73,

Casey, KS7J, Trustee K7FFF, FISTS Northwest, #4400, CC# 457

You do theoretically need a music license if you're going to play any copyrighted recorded music. I don't know offhand of ASCAP or BMI trying to enforce this - but they *have* enforced it in a lot of other places you wouldn't expect (like people playing a music-format licensed station in a bar) so I'd be leery of high-profile Internet musiccasting...

This is one of the most appropriate and on-target comments about eBay,
and auctions in general, that I've ever read.

One kind of item for which eBay has actually improved the auction process
is phonograph records. The customary way for auctioning them has been
for the seller to send lists in the mail, and bidders submit their bid.
It's not a highest bid with a proxy system like eBay--what you bid is
what you bid. You never know if you're bidding high enough or not until
it's over. And you don't know if you're bidding way too high or not.
eBay has actually improved the auction process in this one regard.

2506. HF Antennas and ICE STORMS

Newsgroup: rec.radio.amateur.homebrew

Are you looking for a solution to salvaging your antenna next time an
Ice Storm hits?

For those of you who would like to HOME BREW THIS ANTENNA. I will
provide an assembly manual, parts list with photos and drawings.
I have been retired for the last two years (with a lot of time on my
hands) and have developed a 2 element Delta Loop Driven Array Antenna
with a F/B Ratio 4.5dB greater than a conventional quad antenna.

The 15 and 20 meter version will be available in Spring 1999. The 12 and
17 meter version will be available in the Summer of 1999.

You can view a photo of the antenna, performance charts and graphs and a

further overview of current 10-meter activity on my web page:

http://homepage.interaccess.com/~jpearl/DeltaXray.html

Or search ALTAVISTA or INFOSEEK or LOOKSMART first page under
"10 meter 2 element delta" (in quotes)

The manual is a step by step format.

Will provide a price list (10 meter version) for any hard to find parts
upon request.

The manual with parts list (FOR THE 10 METER VERSION) IS 25 PAGES OF
TEXT, PHOTOS AND DRAWINGS for $10 POSTPAID in USA.

Thank you,
73

While a broadcasting licence may not be required, caution is still
required if you are broadcasting music subject to copyright (which most is).

Folks,

Do any of you know a good source for replacement 572B tubes? I'm told that the Svetlana tubes may cause problems in the Yaesu FL 2000B and 2100B amplifiers due to their slightly higher gain and different bias requirements. I don't really want to modify my unit when the tubes are replaced if I don't have to....

I did a quick search of TechAmerica's site <www.techamerica.com> out
of curiosity. They didn't list that specific item but they did list a
couple of dtmf decoders under 5.00 US as I recall.

Hope this helps...

My 1958 "New Sideband Handbook" discusses another method. This method used vacuum tube technology. In this method, the recovered audio itself is used for phaselock control of the local demodulating carrier. Originally intended to demodulate amateur DSBSC signals, the existing carrier is ignored, even if it is present. A non-limiting audio phase detector is used on the audio I & Q channels obtained from a quadrature demodulator scheme.

The problem that I saw was that if there was momentarily no speech or music, the demodulator would immediately begin to drift. Since little has been heard of this method, I suspect there were severe problems.

This is similar to a Costas loop, except that the signal can disappear.

If you can find a source for the English magazine "Electronics & Wireless World", you will find several articles written in the 1970s about this subject, and using various approaches. In the September 1989 issue is an article and schematic of a fancy add-on demodulator using the limiting method.

All the am synchr demods I have tried works better than envelope
detectors for low signal input, ie. when the signal fades out you still
have quite good receiption using am synchr detector but hardly can copy
the signal with the envelope detector

The only types I have tried are Motorola MC1351P and Texas Instr.

The limiting method works as well as any other method with weak signals,
and better than an envelope detector. PLL types can indeed foul an otherwise
great listening experience if the circuit can't maintain lock...

Noise can be a problem on weak signals, but heck, if a limiter method sync
detector can't provide a listenable signal, then it is time to tune
away...And noise modulation on the carrier CAN trip up a PLL even if the
signal isn't especially weak.

Good Luck with your library search!

Unless you base the design on application of certain components*) I
don't see any reason to use the Clapp type oscillator, several much
better designs have been published during the last 50 years.

*) one such application is a very stable 35-40MHz oscillator using
RG-174 coax cable instead of coil.

And you never know who you're bidding against.... Even if it's the original seller..shilling.

I know of at least one case in the RADIO arena where eBay found a man using multiple accounts to shill and booted him off...errr, well...almost. Many of us are sure he's still selling and probably shilling under another name. eBay now will do little about it!

wireless....

I agree that it is a sellers paradise there. Once in a great while you
can catch the bidders off guard as I did when I bought a radio from there. I
actually paid about the right price or maybe a little less considering he
also had about $150+ in accessories. The nice thing about ebay is that you
can check the sellers track record (if he does a lot of business on ebay).
This is a very nice feature that set me a bit more at ease. I was very
satisfied with that particular deal.

Just use the din plug where the packet or RTTY connector goes. In fact, I've got an MFJ-1278 connected to mine and it all goes through the same cable. Get the manual back and it will give you the pinouts for the connectors on the back and you can figure it out from there.

One warning, on my 990 if you leave the din plug in but turn off the TNC, no audio will come out of the speaker on the rig. You either have to unplug the din plug or turn on the TNC.

Sorry, I was tired. I'm looking to tweak maximum performance out of one.
Seems as though a PLL would work best for very low-level signals, where
there isn't enough signal to overamplify and limit, but not very useful
if there's significant noise on the signal.

So, some specific questions, though general kibitzing in other areas is
encouraged:

1. Did anyone build the circuit in the July 1993 QST? Comments on the
"synchronous" vs. "pseudo-synchronous" modes?

2. It seems logically inconsistent to use a PLL at all from all this;
the times when there's good signal but also noise make the PLL run funky,
and the times when there's little signal there's going to be low S/N and
thus at least some PLL lock problems. Am I missing something or is this
a valid conclusion?

3. Leaving out noise generated by the circuitry, is it logical to assume
that all significant noise on the input signal is algebraically added to
the signal (as opposed to actually modulating it in some way)?

What is the quality of an AM synchronous detector compared to a
standard SSB gear (provided sufficient frequency stability) ?

How about independent side band reception, e.g. the lower sideband to
the right stereo channel and the USB to the left channel. The R2 style
direct conversion receiver would not be too hard to modify for ISB (in
fact one mixer would act as a synchronous detector and the other mixer
would run in quadrature as a phase detector and provide control
voltage for the VCO and the LSB and USB would be generated by adding
resp. subtracting the mixer outputs).

Anyone who can be shown to have aided any illegal activity is at risk of prosecution, amateur licence or not. If that person has an amateur licence, then the prosecution gets the added help of documentary proof that he was well aware of the licensing issues applying to radio transmitters, and even passed exams on the subject. This might make a court lean towards heavier penalties and less likely to acquit. Loss of an amateur licence may be small in comparison to the other outcomes.

Exalted Carrier SSB reception -ECSS- was a
technique used to receive weak and noisy signals
before radios like the Sony 2010 came along. With
the new DDS radios capable of tuning in single
herts steps, you can zero beat the signal and stay
on frequency indefinitely...If you don't mind the
narrow bandwidth of sideband filters it is a great
way to hear those battered DX signals coming in
with auroral flutter and other effects. A syncro
detector, though, would save you from the task of
zero beating your prey IF there's enough carrier
available.

My frequency-synthesized (100 Hz steps) Collins 651-S (vintage 1970) operating in SSB mode does this quite well. I can often reduce adjacent channel splatter interference by selecting upper or lower sideband. The SSB filters (2.7 kHz BW) eliminate the 5 kHz beat note between stations that are 5kHz apart. Because the SSB filter rolls off sharply below 300 Hz, low frequency noise is greatly reduced. With fine tuning (the BFO is synthesized in 10 Hz steps) the speech and music quality are acceptable, but of course not ideal (but then nearly all SW BC stations are right on their assigned carrier freq). And of course there is no threshold effect in SSB reception. If I want high quality music listening I am not going to be on the SW BC bands (or on the 651-S).

Subject: ** FLEA at MIT ** Sunday September 20th Cambridge MA
Summary: Buy Sell SWAP Ham Radio Electronics Computers 9AM - 2PM

This coming Sunday...

*** !!!! In our Traditional GARAGE and lot !!!! ****
so come rain or shine or super heat the Flea is on !!!

********* $1 buyers discount with hardcopy of this notice ********

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday September 20th 1998
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $4 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $10.00-each at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 146.52 and W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)
MIT Radio Society (W1MX)
Harvard Wireless Club (W1AF)

Pat:

Have you thought of re-transmitting the correction information that the
USCG transmits in the 285 to 325 KHz beacon band ??? In theory, you
would need a DGPS receiver (I was involved in the development of one
that is currently being sold by Furuno and CSI) with antenna, a packet
TNC, and a tranceiver. It should not be too hard to get working, if you
can receive the MSK data from a nearby USCG beacon tranmitter.
I am not too sure is this would be legal under current amateur radio
regulations but perhaps the ARRL could advise you.

Sounds like you want a VHF aircraft receiver.(I assume you mean MHz (megahertz), not mHz (millihertz))

Is GLB electronics still around? If I remember, they used to have a single channel receiver for the low-altitude weather satellites---somewhere around 136 MHz.

There was another place---Hamtronics, I think?---that made similar devices.

Wow...this all sounds great but...I hope I don't sound like a putz by saying this...I'm not that skilled in the field of homebrewing. Making the copper cactus antenna was very simple, but this sounds a little more complicated. So, would anyone be willing to get me some written instruction or point me in the direction on how to make a stub? BTW, I don't have any test equipment, so please let me know what, if anything, I'll have to get my hands on.

And even if noone has the time or will to give me farther instructions...thank you very very much for your input.

Very interesting thoughts, Mike, and congratulations on your code improvement.

Regarding special event stations not working the Novice segments, I can think of a few possible reasons: First, there is the power limitation in the Novice segments. Second, 10, 15, and 80 meters aren't the best bands propagation wise. Third, the Novice portion of 40 meters is only available in ITU region 2, and practically unusable after dark. Regardless, I don't think that any of the special event stations are malicious. We frequently hear the following 2 complaints: why don't they work more of the CW bands; why don't they work more of the phone bands. Seems you can never please everyone. Why not volunteer for your club's next special event, and work the Novice bands?

I frequently work the Novice bands myself. Hope to catch you on CW!

Mike, AA3RL

do any of you guys know what is the in stock replacement part for the fet transistor in the front end of the dx 390? the people at radio shack are no help. they no longer keep a cross reference for their own transistors. they keep two fet's in stock . one is 2n3819, and the other is mpf102. i am looking for the part to replace 2sk212.
ii's interesting what happend to my radio. i was listening to it when the house cat came and brushed the radio a couple of times and it just went dead! it must have been static that killed it because i read that the fet in the front end is very static sensitive. the set works with an external antenna but the rf gain control is not working any more. the whip antenna does nothing

For Sale: Vectron 718Y2828 10 Mhz Oven Controlled Crystal Oscillator. New mfg. Power 12VDC, output 5volt P P sine wave into HI Z load. Very small package, ~2"X2"X1" power connections solder pins, RF out SMA, mounts via 4 studs on bottom of package. Delta Frequency adjustment available via screw driver adjustment. Vectron data on 718Y2828 indicates 2E-8 aging rate per year and 2E-8 stability over temperature range. Measurements on my HP 5370A with HS option clock confirm the stability, Unit consumes about 150 MA upon application of power and then drops off to around 75MA after warm up. With hookup documents, $35

Post Paid conus.
Tnx for the read es 73

Decoding these signals is pretty easy, but encoding them is a bitch.
The encoders are very expensive. They haven't been reduced to a
commodity chipset yet, and the serial data rate into them is very
high (1.4 Gbit/sec for broadcast HDTV).

>Maybe we can hack those dish receivers from Sony and RCA. And I
>don't mean pirating HBO. Suppose these satellite receivers use an
>IF of 70MHz. remove the dish and downconvert from some ham band
>digital TV signals into the box's IF amp.

I think the first IF is in the 1 GHz range, same as most analog satellite
TVRO receivers. (The latter can be used directly for 1.2 GHz amateur
FM ATV.)

>Maybe a digital voice communication mode? FM and SSB are kinda
>getting old. A mode that "gets thru", like they say code does.

The main reason the code "gets thru" is the very low data rate it employs.
While better codes do considerably better than Morse, the high data rates
needed for realtime voice or video still impose a SNR penalty. We can get
about a 10 db advantage over analog VSB with 8VSB digital video, and we
can push down to some pretty impressive CNR numbers with digitally
coded FM video, but the information rate is still awfully high, so the
corresponding SNR still has to be fairly good to get good results.

Digital voice is somewhat better. The information rate doesn't have to
be horribly high unless we want CD quality. There are available CODECs
which work with as low as a 2400 bps data stream, though voice quality
leaves something to be desired. We can beat analog SSB by about 9 db
(average power) using ordinary 2400 baud FSK. Better codings can do
somewhat better than that.

On HF, we need to use heavy symbol overloading to get the basic symbol
rate down below 50 baud to avoid skywave multipath distortion, however,
and that means a lost symbol costs us a bigger gap in the speech. If we
were allowed to use SS on HF, we could dodge multipath by frequency
diversity instead, and not have to pay that penalty. Unfortunately, we
aren't allowed to use SS on HF, so we have to fight skywave multipath
in other ways.

Does anyone know where it is possible to obtain smoothing chokes for valve HT PSUs? I have a PSU containing two identical chokes, one of which has gone open circuit. It resembles a transformer with a lamination pack 3 Inch by 2.5 Inch by 1.25 Inch thick. It is wound with about 220 ohms worth of 10 thou wire. I reckon it must be about 12 Henry, but have yet to do the calculation..

Hopefully I can rewind it, as it has E and I laminations and was easy to dismantle, although I had to take a hacksaw to the windings. The problem is it has no former and relies on shellac? impregnation to support the straight sides of the winding. I can make a former from thin plywood, but it will restrict the number of turns.

In case I don't succeed, or decide to take the easy way out is there somewhere where I can obtain a replacement item, or get it professionally rewound at a reasonable price.

I know that Maplin can supply a choke, but it looks too small, both physically and in inductance value.

Many Thanks.

73s de Graham G4ILN.

I can't help with the name of a shop over there, but over here I've taken
such beasts to the local electric motor rewind shop and they've rewound
cores for me. Try checking with electric motor rebuilding shops in your
area. (Generally the small ones are more willing to take on an odd job
than the big outfits.)

Source record: 78986

Hello,

I'm looking for a book (or whatever) that would contain
"full" data sheets and possible application notes on the
vacuum rectifier (diode) tube. Stuff like voltage drop
curves, mounting positions allowed, ratings in air, cooled
or immersed into oil, example schematics etc..

I do know the basics (like 25kVpiv 300mA average etc.)
but not enough data to use the tubes in a HV power
supply I'm building.

I have seen reprints of tube manuals and new books
on some webcatalogs (like tubesandmore site) but they
don't (and can't, of course) list any more info on
how good info books have on tubes (and which ones).
Anyone have comments on following books:
WE tube manufacturing
WE tube data, 2nd edition
I'd buy a book with specs on HV rectifiers like
the 371, 705, 8020 etc..

If someone has the data on 371B and is willing to
scan/photocopy the pages, I'm interested!! Will swap for
HV diodes or something, if necessary. :)

Thanks,

Kristian Ukkonen.

Still believe white-noise could be a serious problem, noise curtains cannot be filtered at your end, it must be 'filtered' at the transmitter, usually the first step is to use sufficient decoupling capacitors on PA supply voltage - and slow down PLL-loops.

LA6LCA mentions that he has to solve a 70cm local packet radio node problem, the radio is something TEK...(?) and the noise spectre is 30dB below carrier MHz-vise out. He has to build proper TX equipment or go QRT on 70cm ssb because the packet rubbish totally spoils his weak-signal receiption with noise curtain emission. -30dB noise spectrum from an FM transmitter is not acceptable, one would not accept 40dB ssb carrier/unwanted sideband level, even when it is on rather limited spectrum

I remember having a 2m digipeater 300ft away from the QTH, it spoiled 2m ssb/cw receiption, but when I installed an alternative digipeater in my own house I suffered very much less problems. No more white-noise curtain and of course, the application of proper rig and antenna reduced the amount of retries.....

To find the inductance just measure the inductance of its twin.

But the exact value of inductance is not of importance. A shift of 25% downwards will not be noticed. A shift upwards could be beneficial.

Take careful note of whether there are intentional gaps in the magnetic path. It will be important to re-assemble the laminations in their original positions. Were the E's and I's alternated so as to produce no gap?

If there is doubt about enough room to wind on the same number of turns then it will probably be OK to use the next smaller gauge of wire. Did it run fairly cool ?

Source record: 79002

Might be old hat to some of y'all, but in the process of diagramming an old transistor radio for a project (where I substitute a stage at a time instead of trying to debug them all at once), I discovered a neat concept.

In old (discrete) transistor radios, it was popular at one time to use defective transistors as diodes because it upped the transistor count, and the public was sold on the "more is better" idea. So I wasn't at all surprised to see a 3-pin "diode" where the AM detector should be.

But then it hit me: it was wired into the circuit with the collector and base shorted together, using the one-way conductivity between C and E to rectify, but losing only Vcesat (ASCII should have been designed with subscripts :-) rather than a full junction drop in the process.

Anyone run across similar nifty tricks? Anyone have a better way of doing the same thing cheaply? And for that matter, are there any devices with unusually low Vcesat? (I usually just guess a rule-of-thumb 0.2V because I seldom have to bias anything that goes saturated; I have no real idea if there's significant variance in real-world devices.)

I don't see how this would work. The voltage would need to rise to
the point where Vbe is one diode drop before any base current flows,
and thus before any collector current flows. Once collector current
does flow, it robs current from the base - so I don't see how the
transistor would *ever* get into saturation.

So I think you still have a diode detector with about 0.6 V drop
across it. But the "knee" in the response might be unusually sharp,
sharper than a normal diode, because of transistor action.

Dave

I haven't yet figured out why this has to be true. One of the things I
plan to play with is biasing the diode into an always-conducting state.
(Currently sacrificing an old discrete transistor radio to various
experiments.)

I see what you're saying, but I was on the noise subject. Feed a PLL a
dirty signal and you get funky locking, time constants or no.

True, if you set it up to free-run at the right frequency, it won't be
long at all in re-locking when a clean signal reappears. But take the
weak signal and add some significant impulse noise to it, and you're at
the thought-place I wrote my comments from. I have this mental picture
of the VCO control voltage waveform looking like a Metallica broadcast
every time the neighbor's fluorescent light ballast hits the airwaves.
That's why I say it seems great in theory but can't understand how it
works well in practice.

This subject was researched thoroughly by S.O. Rice at the Bell Lab in the early 1930's. His paper on this subject is considered a "classic" that is still referenced in many text books.

Back in the days when only women wore earrings and men walked the surface of the Moon, the Motorola HT-220 was the hottest handheld on the market when it was introduced in 1969. Tougher than a pit bull, this VHF or UHF business band handheld in a weatherproof housing was the envy of ham radio operators for its compact size and performance.

Crystal controlled!
Discrete components! (exception 2 ICs)
HT for 'Handie Talkie'!

with that much forward gain, what is your reverse gain? is the preamp unconditionally stable? does it perform
under contest conditions? the 3sk48 has nearly 30db forward gain but has less than 24dB reverse gain. not very
stable.

these questions i hv found to be much more important than lowest NF and highest gain on 2 meters.

Be aware that if the cat can zap it, you may have the same trouble trying
to solder it in. MOS transistors can be kind of touchy. Might be best to
have someone else repair it.

Anyway, You're looking in the wrong catalog. The pegboard stuff is just
floor sweepings so that RS can claim to be following the long tradition
as a parts supplier.

But they are actually pretty good about supplying repair parts for most
of their assembled units. Check in the special order catalog kiosk,
if your store has one. One catalog lists, in Radio Shack catalog number
order, the major repair parts for that unit. You fill out the data on
a slip and get the salesdroid to place a special order.

You can even deal with Tandy National Parts over the phone if
the salesdroids at your local store are too clueless. Try either
800-THE-SHACK and get a live operator to give you the number or try the
800 directory assistance for Tandy National Parts. There may even be
a link in Tandy's web pages.

If you don't want to deal with them, the part's available from
distributors that specialize in repair parts for consumer electronics.
MCM, Dalbani, Premium Parts, and so on. Try http://www.repairfaq.org
for a more complete listing of these outfits. (it's down temporarily I
think, see the sci.electronics.repair newsgroup for status). The last
MCM catalog I have has the 2sk212 back in the japanese semi section for
about a buck, but that was a couple of years ago. www.mcmelectronics.com
and www.dalbani.com are a couple of web addresses.

As a last resort, try looking for whoever repairs Sangean radios, the
real manufacturer.

Have a look at http://www.seits.org/seits/duplexer/duplexer.htm
This page describes a notch+bandpass filter. It seems to me that one cavity may be all you need to suppress pager intermod. If you can knock the pager signal doiwn by 20 db then the intermod should go down by 60 db. The filter may even be constructed from coffee cans if you aren't after absolute minimum notch to passband spacing.

2583. How to bring up 20 year old 3-500 Transmitter tubes

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-16 00:00:00 UTC
From: af4z@palmnet.net
Message-ID: <6tn3l6$k7k$1@news5.ispnews.com>
Source record: 79060

Is there a safe or preferred way to being some old tubes 3-500s (Date code 7609) back on line?

I have a Henry 2KD-3 that has not been used in 15 -20 years and I want to get it up and going. I have the supply checked out and I have powered the filaments for an hour and they look fine. I saw sometime back a discussion on this subject but did not save the info. Is there a recommended procedure?

Don AF4Z

>1. Did anyone build the circuit in the July 1993 QST? Comments on the
>"synchronous" vs. "pseudo-synchronous" modes?

I did, in editing the article for QST, and for the ARRL Handbook, in which it appeared in the 1995 through the 1997 editions (think it's in 1998, too, but I don't have that edition here). It works quite well. In my opinion, however, it doesn't hold lock on fades quite as well as the sync detector in the Sony ICF-2010 -- but then that may be due, in part, to the 2010's very-fast-decay AGC, which was approximated by none of the radios with which I used the detector. (BTW, the Sony circuit is based on a proprietary IC originally developed for AM-stereo demodulation.)

Jukka Vermasvuori, the author of the 1993 QST article, is a broadcast-engineering professional with YLE (Finnish Broadcasting). His "Quasi-Synchronous Detection" sidebar explains the difference between synchronous and pseudosynchronous detection well. Both modes make use of heavy limiting, but for different purposes. The importance difference is that in pseudo/quasisynchronous detection, the limited signal serves to heterodyne the sideband energy back to baseband, whereas in (what we call for this discussion) true synchronous detection, the limited signal serves only as the phase reference for a PLL, the VCO in which serves as the heterodyning signal. The latter technique is better because the loop filter acts as a flywheel (as a memory, if you will),insulating the detector from sudden phase shifts due to propagation and modulation. Merely limiting the signal to provide the heterodyne results in significant degradation during such phase shifts, and when the signal is not sufficiently distinct from noise.

I recommend the QST treatment over the Handbook treatment mainly because it contains everything we had to say on the subject; the Handbook treatment was necessarily condensed.

>2. It seems logically inconsistent to use a PLL at all from all this;
>the times when there's good signal but also noise make the PLL run funky,
>and the times when there's little signal there's going to be low S/N and
>thus at least some PLL lock problems. Am I missing something or is this
>a valid conclusion?

Sync detector behavior can vary so widely with design and alignment,
as well as being affected by the AGC dynamics of the asociated
receiver, that I'd hesitate to make such a sweeping conclusion.
Sometime in the past five years, a QEX article or articles generally
surveyed synchronous detection and detectors; if you're an ARRL
member, you can search for that article in the QST/QEX database
availabable in the members-only portion of the ARRL website
(http://www.arrl.org/).

>3. Leaving out noise generated by the circuitry, is it logical to assume
>that all significant noise on the input signal is algebraically added to
>the signal (as opposed to actually modulating it in some way)?

Yes, if the "product detector" (multiplier) driven by the incoming
signal and PLL VCO isn't overdriven to the point that it fails to act
as a linear frequency shifter. Using the detector at the end of a
reasonably-well-AGCed IF strip and properly adjusting the signal level
applied to the detector's makes such overdrive pretty much a
non-issue.

Comment: It's funny-odd how, growing up with putting up with selective
fading distortion, we tend to enode into the romance of shortwave.
(And in the romance of long-distance mediumwave reception, too, if you
can stand carrier troughs *minutes* long.) Nowadays, having listened
to shortwave with good sync detectors and with good, stable, wideband
SSB receivers, my tolerance for selective-fading distortion is quite
low. I'd rather listen to the Beeb through an SSB-class bandwidth with
no selective fading than put up with "higher-fi" envelope reception
that's periodically, momentarily and often ruined by distortion from
carrier troughs. Which manufacturer of DSP-equipped ham transceivers
willl take the time to write a bit more detection code and build in
DSP-implemented sync-AM detection?

For Sale.......

1947 ARRL Radio Amateur's Handbook, very clean,
shows only the very slightest use. No dog ears!
No stains, ink marks, missing pages, or musty
oders. Binding is perfect..... $25.00

I'll pay the postage in USA or Canada.

email - me

2589. How about some new modes of communications on ham bands?

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-16 00:00:00 UTC
From: wa2ise@netcom.com
Message-ID: <wa2iseEzD4GE.441@netcom.com>
Source record: 79066

How about digital amateur Television? Using MPEG compression (the sort to be used in HDTV)?
Maybe we can hack those dish receivers from Sony and RCA. And I don't mean pirating HBO. Suppose these satellite receivers use an IF of 70MHz. remove the dish and downconvert from some ham band digital TV signals into the box's IF amp.

Maybe a digital voice communication mode? FM and SSB are kinda getting old. A mode that "gets thru", like they say code does.

2590. Re: Difference between Icom IC-720 and IC-720A

AFAIK The 720A has a vastly improved synthesizer and thus much lower
phase noise. Stay away from the early 720 and get a 720A.
Thats my suggestion....
Cheers

I had just read the article a couple of hours before posting these questions.
I have no idea how my feeble brain made "pseudo" out of "quasi". :-) Have
it here, as a matter of fact, pp. 28-33.

I can see that... in the absence of significant noise. Having been foolish
enough in the past to try to get PLLs to lock on noisy signals (especially
those with extra "inserted" zero-crossings), I can attest to the funny
things they can do, and it gives me this mental recording of some really
weird sounds. I also have trouble envisioning the PLL staying well locked
when the signal has become insufficiently distinct from noise, though at
times there's more signal in the noise than anything but a good circuit
can pick out. The PLL seems by far the better idea in theory, but until I
"heard" you say it seems to work better in practice I would not have bet
my pet rock on it.

One of these days I'm gonna crack open the wallet and get a new Handbook.
The newest one in the house is 1979. (Of course, the old ones stay, for
the tube information and other neat stuff.)

Kewl. I would have thought so, but every time I make a statement about the way things seem they should be, someone points out some natural phenomenon I didn't know about or didn't consider. :-) I couldn't think of anything that would make a significant noise source interact with signal in any other way except algebraic addition (though if errant signals are considered noise sources, there are always those chain-link fences that make great near-field nonlinear mixers).

I think the romance comes more from fond remembrance of the wonderful time we had listening to shortwave than from the poor equipment available to us when we started listening, and instead of recalling those missed bits of information during the fades we tend to remember the bits we got. We like to talk about the good old days, but they weren't that good, we weren't that old, and it's not the days we remember best anyway. :-)

<sabinw@mwci.net> wrote:

<Synchronous AM detection vs. SSB>

The reason that I was asking is that while experimenting reception of AM transmitters in SSB (on an IC-706), while the possibility to select the side band and use passband tuning are great to reject man made interference, I did not notice much (if any) improvement in readability (and apparently also SNR) when listening to a single weak station in wide band noise without interference from other transmissions.

Has this something to do with that the sidebands in an AM transmission are correlated (+6 dB), while the wide band noise in the double bandwidth (+ 3 dB) is not correlated, giving a +3 dB net increase in SNR for AM vs. SSB reception of AM ? Does these synchronous AM detectors restore the SNR in presence of only wide band noise ?

: assigned carrier freq). And of course there is no threshold effect
: in SSB reception.

While the threshold effect is very clear when feeding a diode detector directly with an AM signal generator and reducing the signal level. However, the real situation is a bit different, since when the signal drops, the first stage noise (and antenna noise below 100 MHz) becomes stronger and stronger due to a.g.c. action, so the noise constantly shifts the signal above and below threshold. The situation is a bit similar as with the added dither noise in ADCs, so in practice, you can record low frequency tones below -96 dB with a 16 bit ADC. With any AM receiver with diode detection and a.g.c., I have not been able to observe any pronounced threshold effect, although the signal gets very distorted due to all kind of intermodulation product between different audio tones.

I still have have a number of unused oven Controlled Crystal
Oscillators (OCXOs) at 16.384MHz these units came on the market very
cheaply.

Units are in metal boxes hermetically sealed with pins for PCB
mounting, I have an off air standard here and can calibrate ie ship with
information on what voltage to set to to give frequency to +-0.1ppm when
you connect up.
This calibration should be good to 1.0ppm over the next few years.
Dimensions 75X50X30mm
These divide by 2 to the power 14 to give 1 kHz to function as the
reference for frequency synthesisers as used in instruments, radio,
cellular, TV Transmitters..
Oscillators are stable to parts in ten to the nine
a wide temperature band.
Excellent spectral purity, measurement repeats to 0.0001ppm per
second.
Will operate over -40+70C
12 V supply 600mA on warm up. 150mA when running@23C
Output 1.5 v Peak to Peak sinewave AC coupled, 50 ohms source
resistance.
Built in 8V reference so that fine frequency adjustment can be
carried out with external potentiometer.

These units are latest technology and approach Rubidium standards in
stability they incorporate SC cut low ageing
crystals; ageing rate reduces logarithmically and can be expected to
age no more than 1 ppm over the next 5 to 10 years, inital ageing
already complete as units are over 1 years old.
Units within +-0.01 ppm after 10 minutes perhaps better.

sold at approx 10% of manufacturers price.
Supplied tested with connection diagram.

Note sampling PLL circuit diagram available to lock 10MHZ crystal (or
similar freq)to the 16.384MHz

Allow 7 days for delivery price including post $90

> for a device with a Noise Factor of about 0.5 dB
>
> Thanks
>
>
I have been looking at this. The Siemens CF739 Gasfet seems to fill the
bill at low cost (get a data sheet from the Siemens website)
I built a preamp using this device with a tuned input (inductor 100nH
tapped at 1:6 with a 10p variable cap) and a broadband output (use a 3:1
transformer ie 9:1 impedance ona VHF ferrite core) I also used a couple of
2 stage helical filters.
With 8V and about 20 mA I got +12 dBm out.and a gain of about 25 dB. I
havent got the gear to measure the noise figure but in theory it should be
around 0.7 dB
The device is surface mount but I find these easier than thru hole parts
now!

Hello, I have the following literature that is out of print,
and very hard to find. These are very high resolution LASER
monochromatic reprints of the rare originals. All are professionally
done with original style binding. All sales final on literature,
and I'm sure you'll be pleased. All prices INCLUDE POSTAGE, in the
continental USA. Others by actual quote.
Thanks, and if you need tubes, visit our sister screename,
Tubecntral@aol.com

TRANSFORMER BULLETINS/CATALOGS/MANUALS:

KENYON "Quality transformers",23 pages,has some writing in numbers
on the front cover by the original owner,but a real information
getter. Covers ALL transformers available in Dec.1st,1941.
Even has the "blown in" price update sheet! Price $9.00.

PEERLESS Transformers, Catalog 1948 - 1,original owners name
on upper right hand corner, nice info, not perfect but nice,
Price $8.00.

SNC Transformers, January 1, 1947,13 pages plus original owners name
spelt on upper right hand corner,beautiful copy, has "blown in"supplimentary
catalog page,price sheet, and August price update sheet! Price $8.00

STANCOR Essex #2,069,42 pages, a REAL NICE MANUAL/CATALOG,has EVERY thing!
A real good info source,Price $10.00

STANCOR Essex Catalog # 140 H, 21 pages plus Numerical index and
October 1, 1948 price update list, very nice, $9.00

THORDARSON "Transformers by Thordarson, No. 400-FX 1942, A beautiful
source of info, 27 pages, Price $9.00

THORDARSON 1941"Tru-Fidelity by Thordarson, an UNBELIEVABLE catalog, real
nice pictures of early Broadcast transmitters and an excellent source
of audio info, 19 pages,real nice. Price $10.00

UTC Transformers, reactors, filters, Catalog# 500,looks like early 40's
another real nice, illustrated Catalog/manual, 22 pages, Price $9.00

UTC transformer components, Spiral-bound Excellent catalog/manual,
really in depth, Bulletin# PS-405,)ct. 15, 1941, includes "blown in"
price update for Dec. 6, 1946.Another excellently illustrated info
source, 34 pages, Price 11.00

EITEL-McCullough's "THE CARE AND FEEDING OF POWER TETRODES", 1951
25 pages crammed full of information IN DEPTH! Has everything you
ever wanted or needed to know about running these tubes, a real

nicely illustrated easy to understand manual, Price 10.00
Thanks for reading, if you have any questions or need to order,
Please respond to my mailbox...
Thanks, Joe Pratt,

An AM transmitter puts one half of its total sideband power in each correlated sideband, so when we listen with an SSB receiver we get 6 dB less audio output. The noise power in the SSB receiver is 3 dB less. So, as you say, there is a 3 dB loss in S/N when listening to the AM station with an SSB rcvr. In the HF SW BC environment this penalty is nearly always trivial (in my experience), unless *perhaps* when you are logging very weak signals that are in the clear. The advantages of using the SSB rcvr tend to override this 3 dB loss in most cases.

And if the signal is very weak, the ability of a PLL to lock-on becomes a problem, as others have mentioned. Also, the PLL should have a very narrow bandwidth to avoid interactions with the AM sidebands. And for this reason the xmtr AM sidebands should drop off quickly below about 300 Hz or so, which they do not in SW BC.

> shifts the signal above and below threshold.

If you feed a gradually increasing unmodulated carrier level into an AM receiver with an envelope detector there may be an increase in noise output as the diode detector begins to function. This increase is due to noise intermodulating with itself. When this occurs the AF noise output from the detector has an approximately 1/f characteristic, and an

attenuated low frequency audio response is therefore helpful. An envelope detector needs a fairly strong carrier to completely suppress this effect.

If the noise is strong, and there is no carrier, then this noise-noise intermodulation is quite pronounced and it is the only effect that is occurring. As we introduce the carrier the noise may show some slight increase and then start to decrease, or it may immediately start to decrease, depending on whether the rcvr is making AGC on its own internal or atmospheric noise (good AM rcvrs do).

In any case, as the carrier becomes strong the C/N ratio approaches the same value as the product detector, but initially the C/N ratio is *worse* than the product detector.

For the envelope detector, a significant carrier is needed to drive the detector into linear operation and suppress the noise-noise intermodulation. The product detector, also the PLL detector, does not have this problem.

The 3 db gain against noise uncorrelated in both channels holds
whether you're facing gaussian noise or off frequency interference.
The only criteria is that the desired signal be symmetrically correlated
around the carrier while the interference is not symmetrically correlated
around the carrier. However, the gain is only 3 db, and the ability to reject
interference occuring in only one sideband by more than that using a
SSB filter is often of greater value.

Theory says that true synchronous detection is 3 db better than pseudo-
synchronous. If we implement all the time constants properly, it really
is. But if we don't, then it can be an appalling mess as the loop drops
in and out of lock.

>and the times when there's little signal there's going to be low S/N and
>thus at least some PLL lock problems. Am I missing something or is this
>a valid conclusion?

The short answer is yes. I had a hard time getting the time constants
to behave appropriately on a real shortwave signal with fading. Note:
I spent a good deal of time tweaking the articles component values for
consistent performance.

The only real advantage was that for a ground wave MW station without
any selective fading, the audio sounded very good. The usual diode
envelope detection circuits can introduce amazing amounts of
distortion even with no noise to modulate them.

>3. Leaving out noise generated by the circuitry, is it logical to assume
>that all significant noise on the input signal is algebraically added to
>the signal (as opposed to actually modulating it in some way)?

Again the short answer is yes. However, most envelope detection
circuits (particularly the single diode detector circuits) sound much
worse than they have to. Even with very little noise, many of these
detectors can distort the recovered audio. An envelope detector with
reasonable IF decoupling and a clean audio amplifier can sound
surprisingly nice. This is why so many folks find radios like the
YB400 (with an envelope detector) an equal to the Sony 2010 (which
uses synchronous detection).

automatic detection of full charge is hard, max713 and 712 uses
microcontroller to check the voltage and temp over the time to detect
full charge state.

It seems quick charged nicad has a short life than a slow charged one by
200-300 cycles.

2606. Space Listening on ordinary worldband???

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-17 00:00:00 UTC
From: bartalzo@hem2.passagen.se
Message-ID: <6trmuciuu1@nnrp1.dejanews.com>
Source record: 78936
Cross-posted to: rec.radio.shortwave,rec.radio.amateur.equipment,rec.radio.amateur.space,rec.radio.amateur.homebrew

Hello, here's 3 questions I would like to be helped with:

1. Is $250 a good price for a Sony ICF-SW7600G?

2. Does someone know any frequencies of particular space missions/satellites/sonds?

3.Is it possible to homebrew a unit which could expand a normal AM frequency range (150-30000 kHz) to 100-300 MHz or more, so that it would work by connecting it to a normal worldband radio?

I appreciate help. Please return a possible answer to bartalzo@hem2.passagen.se, as well. Thank you.

Greeting from Zoltan, a VERY beginner radio-amateur whose knowledge in radiotechnics and electronics is VERY limited.

This radio is nearly twenty years old, and because of its sensitivity
(relative to other cheap transistor radios) saw an awful lot of hours
of power-up use before I dropped it a few years ago and somehow missed
a crack while repairing it. Now that I found the crack while diagramming
the circuit, it will see lots more. But, I cancelled the article you
replied to soon after I sent it; see the article I replaced it with for
more information on the circuit.

Do you mean they were failing, or that it wasn't long before you stuck a
diode in their place? If the former, why do you suppose they were going
bad?

IIRC, there was a lot of talk about this failure mode a few years ago in
rec.radio.shortwave, but usually from atmospheric static and not from
feline sources. :-) A DejaNews search should turn up articles for the
original poster about how to not only substitute the transistor, but also
to add protection against recurrence.

I believe it was because of the reverse voltages between the collector and
the emitter junction tends to be far less than a diode if the base and
emitter are shorted together. Something like that, it's been a few years.

You can use the common MPF-102 for the blown FET in the DX-390 front end. (That is what I did when mine got zapped.) I think RS still sells them for about $.99. BTW, there is no performance difference.

Also, when I had the radio apart, I took the opportunnity to add a couple of diodes as a clamp across the antenna to prevent it from happening in the future. (Still going strong after three years later.) Here is a crude ASCII schematic:

```
\|/
|
+------+--------+------> normal front end circuitry
| |
| |
----- -----
\ / ^
v / \
----- -----
| |
| |
+------+--------+------> Ground
|
///
```

I used ordinary 1N914/1N4148 Si diodes. You probably don't want to use Ge (e.g., 1N34) diodes as the clamping voltage will be low enough that it might cause problems.

>missions/satellites/sonds?

My home page has a list. Also go here:

http://www.amsat.org/amsat/sarex/shutfreq.html

But just to help right now:

Space Shuttle/Mir Radio Coms - As of: 8/23/98

(Sarex is now known as the Space Amateur Radio EXperiment)

Space amateur Radio experiment (Sarex) Downlink: 145.550 FM
This is for both voice AND packet modes. So if you hear short
bursts of noise they are in packet mode.

Some amateur radio 2 meter FM repeaters carry live air to
ground coms. Go here to get a list of shuttle freqs around the country:
http://www.amsat.org/amsat/sarex/shutfreq.html
If your in the NYC metro area try the W2FCL repeater in Northern N.J.
on 146.610. I pick this repeater up from about 100 miles away easily on an
Icom 2000H and a Ringo Ranger vertical up about 27 feet.

On HF, WA3NAN - the Goddard amateur radio club
re-transmits the missions on: 3.860 LSB (all freqs. in single side band)
7.185 LSB
14.285 USB
14.295 USB
21.390 USB
21.395 USB
28.650 USB

These are dependant on propagation! In South Eastern N.Y. I pick them up on
the 80 and 40 meter frequencies (the first 2) the best.
They I.D. in morse code and voice. Park on a freq. and listen awhile,
coms are not non-stop! There are sometimes long breaks in the action.
When the astronauts are asleep they are off the air. If the weather is
bad at the station or no control operator is available they won't be
on the air either. This is a volunteer service. Thanks to WA3NAN for
providing this service!

Mir 2 meter FM amateur radio downlinks are currently on 145.800 (Europe)
and 145.985 in the U.S. These are for both voice AND packet radio.
So if you hear short bursts of noise they are in packet mode. They are
in packet mode most of the time, especially after 2000UTC.
(their 8 hour sleep period)

There is a ground control freq. of 143.625 FM that is sometimes
used as well, but NOT for amateur radio. I hope you speak Russian!

Mir is also now on 70 cm with voice downlinks on: 437.950
437.925
Packet downlink: 437.975

Happy listening!

Anyone know of a source for mounting brackets for ham radios in 19" relay racks or consoles ?? I have acquired two (2) Motorola Centracom bays and wish to mount all my hardware and the ham radio computer inside. I have a Kenwood TS-870S that is the #1 item and it apparently has no provision for doing so, so any suggestions are very welcome.

Please reply to stewart1@usa.net or to n4cro@juno.com and thanks for any assistance.

An Asynchronous comment:

I just read through this thread and also reread the referenced 1993 QST article...

And it comes to mind out of dim memory that if one is trying to implement the Quasi-Sync Detector as described in QST, the carrier needs to be bandlimited before amplitude limiting and any resulting delays between the direct and limited inputs to the detector must be somehow equalized or at least the resulting waveforms must be kept in phase...

I note that the article says that this was tried and discarded but, the filters mentioned would not have been narrowband enough in any case. Something around 100 Hz would probably be appropriate.

73,
Marv WC6W

2622. Guide to the rec.radio Newsgroups

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-17 00:00:00 UTC
From: jeffreyh@Hawaii.Edu
Message-ID: <6tqcov$lha@news.Hawaii.Edu>
Source record: 79014
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew

Archive-name: radio/personal-intro

This message describes the rec.radio.amateur.*, rec.radio.cb, rec.radio.info, and rec.radio.swap newsgroups, as well as their Internet mailing list counterparts and complements. It is intended to serve as a guide for the new reader on what to find where. Questions and comments may be directed to Jeffrey Herman, KH2PZ, (jeffreyh@hawaii.edu), or Paul Schleck, K3FU, pschleck@novia.net.

This message was last changed on 14 March, 1998.

History
=======

Way back when, before there was a Usenet, the Internet hosted a mailing list for hams, called (appropriately enough) INFO-HAMS. Ham radio discussions were held on the mailing list, and sent to the mailboxes of those who had signed up for it. When the Usenet software was created, and net news as we now know it was developed, a newsgroup was created for hams: net.ham-radio. The mailing list and the newsgroup were gatewayed together, eventually.

Over the years, as the net grew, the volume of discussion became progressively higher. First one by one, and then as part of two reorganizations, what was once one group became many. In the process, developments elsewhere on the net were reflected in the groups as they were created, most notably the change to place all of the ham radio groups in one hierarchy.

The collection of newsgroups continues to grow as more people join the net, and as more topics of discussion gain volume, I expect to see more groups be created as well. This follows what is happening on the rest of the net.

Nearly all of the radio newsgroups have corresponding mailing lists, the notable exception being rec.radio.swap. There are also a few mailing lists that don't have newsgroups.

The Current Groups
==================

It's important to post messages to the group that's appropriate for them, and not to the groups that aren't. The whole idea of having different newsgroups is so that folks who aren't interested in, say, homebrewing, don't have to wade through messages about homebrewing on the way to read about Field Day. Posting appropriately is just good etiquette.

The rec.radio.amateur.misc group is the catchall. It is what rec.ham-radio was renamed to during the first major reorganization. Any message that's not more appropriate in one of the other groups belongs here, from contesting to DX to ragchewing on VHF to information on becoming a ham.

The group rec.radio.amateur.digital.misc is for discussions related to (surprise!) digital amateur radio. This doesn't have to be the common two-meter AX.25 variety of packet radio, either; some of the most knowledgeable folks in radio digital communications can be found here, and anything in the general area is welcome. The name was changed to emphasize this, and to encourage discussion not only of other text-based digital modes, such as AMTOR, RTTY, and Clover, but things like digital voice and video as well. The former group, rec.radio.amateur.packet, was removed on September 21st, 1993. It is obsolete, and you should use .digital.misc instead (or the appropriate new mailing list, mentioned below). The group has .misc as part of the name to allow further specialization if the users wish it, such as .digital.tcp-ip.

The swap group is rec.radio.swap. This recognizes a fact that became evident shortly after the original group was formed: Hams don't just swap ham radio gear, and other folks besides hams swap ham equipment. If you have radio equipment, or test gear, or computer stuff that hams would be interested in, here's the place. Equipment wanted postings belong here too. Discussions about the equipment generally don't; if you wish to discuss a particular posting with the buyer, email is a much better way to do it, and the other groups, especially .equipment and .homebrew, are the place for public discussions. There is now a regular posting with information on how to go about buying and selling items in rec.radio.swap; please refer to it before you post there. To answer a frequently asked question: No, there is no mailing list that goes along with this group. If you can't read Usenet news directly, you're out of luck.

The group rec.radio.amateur.policy was created as a place for all the discussions that seem to drag on interminably about the many rules, regulations, legalities, and policies that surround amateur radio, both existing and proposed. Recent changes to the Amateur Radio Rules (FCC Part 97) have finally laid to rest the Great Usenet Pizza Autopatch Debate - it's now legal to order a pizza on the autopatch, if you're not in the pizza business - as well as complaints about now-preempted local scanner laws hostile to amateurs, but plenty of discussion about what a bunch of rotten no-goodniks the local frequency coordinating body is, as well as the neverending no-code debate, may still be found here.

The group rec.radio.cb is the place for all discussion about the Citizens' Band radio service. Such discussions have been very inflammatory in rec.ham-radio in the past; please do not cross-post to both rec.radio.cb and rec.radio.amateur.* unless the topic is genuinely of interest to both hams and CBers - and very few topics are.

The rec.radio.info group is just what its name implies: it's the place where informational messages from across rec.radio.* may be found, regardless of where else they're posted. As of this writing, information posted to the group includes Cary Oler's daily solar progagation bulletins, ARRL

bulletins, the Frequently Asked Questions files for the various groups, and radio modification instructions. This group is moderated, so you cannot post to it directly; if you try, even if your message is crossposted to one of the other groups, your message will be mailed to the moderator, who is currently David Dodell, WB7TPY. The email address for submissions to the group is rec-radio-info@stat.com. Inquires and other administrivia should be directed to rec-radio-info-request@stat.com. For more information about rec.radio.info, consult the introduction and posting guidelines that are regularly posted to that newsgroup.

The groups r.r.amateur.antenna, .boatanchors, .dx, .equipment, .homebrew, and .space are for more specialized areas of ham radio: discussions about antennas, the older tube based amateur, military, and commercial gear, commercially-made equipment, homebrewing, and amateur radio space operations. The .equipment group is not the place for buying or selling equipment; that's what rec.radio.swap is for. Similarly, the .space group is specifically about amateur radio in space, such as the OSCAR program and SAREX, the Shuttle Amateur Radio EXperiment; other groups cover other aspects of satellites and space. Homebrewing isn't about making your own alcoholic beverages at home (that's rec.crafts.brewing), but rather construction of radio and electronic equipment by the amateur experimenter. The .dx group is devoted to long distance amateur communications. Each of these subgroups has its own charter and FAQ; please refer to the archives to find these documents.

Except for rec.radio.swap and rec.radio.cb, all of these newsgroups are available by Internet electronic mail in digest format; send a mail message containing "help" on a line by itself to listserv@ucsd.edu for instructions on how to use the mail server.

All of the groups can be posted to by electronic mail, though, by using a gateway at the University of Texas at Austin. To post a message this way, change the name of the group you wish to post to by replacing all of the '.'s with '-'s - for example, rec.radio.swap becomes rec-radio-swap - and send to that name@cs.utexas.edu (rec-radio-swap@cs.utexas.edu, for example). You may crosspost by including multiple addresses as Cc: entries (but see below). This gateway's continued availability is at the pleasure of the admins at UT-Austin, and is subject to going away at any time - and especially if forgeries and other net.abuses become a problem. You have been warned.

Mailing Lists

In addition to the mailing lists that mirror the Usenet newsgroups, there also are a few that stand alone. These cover specific areas of ham radio, and discussion is focused on just those areas.

The cq-contest mailing list is for discussions of contesting in ham radio. To join, send email with the word "subscribe" on a line by itself to cq-contest-request@tgv.com.

The DX mailing list covers the finer points of DXing. This one is also joined by mailing "subscribe" on a line by itself, this time to

dx-request@unbc.edu.

There's also a VHF mailing list, for VHF operators of the weak signal persuasion. You can join this one be sending "subscribe vhf" on a line by itself to vhf-request@w6yx.stanford.edu.

The QRP-L list is devoted to building and operating gear at low-power outputs. To subscribe, send an email to listproc@lehigh.edu and only write: subscribe qrp-l Your Name.

The TopBand e-list is devoted to all areas of operation on 160m. To subscribe, send an email to majordomo@contesting.com and only write: subscribe topband and follow the instructions you'll be sent.
This site, contesting.com, also hosts a couple dozen other ham-related e-lists. Use the above address, and only write: lists to get the entire index.

The Boatanchors e-list is devoted to the older tube-based ham, military, and commercial communications gear. To subscribe, send an email to: listserv@listserv.tempe.gov and only write: subscribe boatanchors

For homebuilding transmitters and receivers using tube technology, there is the Glowbugs e-list; send an email to:
majordomo@piobaire.mines.uidaho.edu and only write:
subscribe glowbugs <your@address.here>

The VHF DX discussion list can be accessed by sending an email to: majordomo@blacksheep.org and only writing: subscribe VHF-DX-discuss.

Qth.net hosts over 100 ham-related e-lists, including lists devoted to each state, manufacturer, mode, band - too many to state here. Send an email to majordomo@qth.net and only write: lists to get the complete index.

For one of the most complete indexes of email lists, see
http://pw2.netcom.com/~ac6v/pageae.html

Please do NOT send subscription requests to the mailing lists themselves; that doesn't work very often, and is very annoying to those on the list. Also, please keep your electronic mail address current with any mailing lists you subscribe to, as dealing with returned email is a nuisance for the person maintaining the mailing list.

A Few Words on Crossposting
==========

Please do not crosspost messages to two or more groups unless there is genuine interest in both groups in the topic being discussed, and when you do, please include a header line of the form "Followup-To: group.name" in your article's headers (before the first blank line). This will cause followups to your article to go to the group listed in the Followup-To: line. If you wish to have replies to go to you by email, rather than be posted, use the word "poster" instead of the name of a group. Such a line appears in the headers of this article.

One of the few examples of productive cross-posting is with the rec.radio.info newsgroup. To provide a filtered presentation of information articles, while still maintaining visibility in their home newsgroups, the moderator strongly encourages cross-posting. All information articles should be submitted to the rec.radio.info moderator so that he may simultaneously cross-post your information to the appropriate newsgroups. Most newsreaders will only present the article once, and network bandwidth is conserved since only one article is propagated. If you make regular informational postings, and have made arrangements with the moderator to post directly to the group, please cross-post as appropriate.

Sowter Transformers of Ipswich make a range of Valve Output and mains transformers and chokes for valve power amps, they have a range of 28 chokes from 1 to 20 Henries as standard and can design others to your spec, they are on 01473 252794.
Hope this helps
John

> -

Ah, but that's the easy way round. Iron transformers for 50Hz get wound with more turns per volt to increase the primary inductance and hence keep the magnetising current down. Reservoir capacitors have to be a bit larger for 50Hz, for the same brownout tolerence. The Japanese mains can dip to 88v RMS and still be within its spec. The difficulty is in making a good robustly tolerenced design that can work on Japan's nominally 100v supply on a low day (and still be usable on another range on the UK's 240v nominal on a high day).

Unless a transformer has very crude, thick, laminations and a poor core material, efficiency is usually noticably better on 60Hz than on 50Hz. Ripple currents in reservoir capacitors will also be lower at 60Hz, leading to less heating and loss of electrolyte water content.

Cheers

2626. D.D.S. questions

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-17 00:00:00 UTC
From: Vincent Habchi <vincent.habchi@art.alcatel.fr.XX>
Message-ID: <3600D103.67F9DD48@art.alcatel.fr.XX>
Source record: 79018
Cross-posted to: rec.radio.amateur.homebrew,sci.electronics.design

Hi there,

I've been - for a long time - interested in building a synthesized
wobulated HF / VHF / UHF signal source.

I found that the most handy solution for both speed and resolution was
the use of a D.D.S. chip, on which various P.L.L. would be locked.

Yet, some questions remain :

- Owning to the narrow band SFDR of 70 dBc (ï¿½ 50 kHz), that means I cannot get
a better phase noise figure for the locked VCO if the loop BW equals or exceeds
50 kHz [Indeed, it will be worse, with the multiplication phenomena].

- An App. Note of Analog D. states that the AD9850 chip has a residual P.N. of
circa -135 dBc/Hz at 1 kHz offset, for a 5 MHz sine generated out of a 125 MHz
clock. How does this figure evolve if I reduce both the output and the clock
frequency ?

- Finally, the trick would be to lock a VCO on the same frequency as the DDS,
with something like a 5 kHz BW in order to remove the spurs of the DDS, then
use the output of the VCO as reference frequency for another loop. Does it
make sense ? I mean, would I get a better phase noise than the ï¿½ direct ï¿½
solution - that is to say without the first 1:1 loop.

Thanks for any advice.

Vincent, F5RCS

Okay, I'll try to make a long story short. You're partly right and I'm partly right too. :-)

I thought I saw less than 0.6V drop there, though I didn't measure very carefully the first time around. I also thought I saw some abstruse DC biasing going on, but was a bit confused by my own schematic (and am still a bit unfamiliar with what's going on, but know enough to address the detector part). The transistor does have some DC bias to the base/collector. At no-signal condition, it's not Vcesat and it's not 0.6V either, it's right in between at 0.4V nice and steady; with signal it varies about that point by .05V plus and minus (medium signal).

So you're right, it's not driven into saturation; but it is driven pretty hard. And I'm partly right, it's somewhat less voltage drop than the usual diode. And it is interesting.

Rough circuit description: secondary of last IF transformer, one side to ground, other to emitter; base and collector connected together to a .02 uF capacitor to ground, and a 4700 ohm resistor to the same bias source supplying the RF amplifier. Biasing source (about 0.7V) supplies current to keep "diode transistor" biased on; "diode transistor" current draw changes bias on RF amp, providing AGC action. RF amp emitter is grounded, and base varies by 0.1V between a very weak and a very strong signal (measured 0.557 for the strong signal, 0.652 for the weak one).

Another interesting goody in this design; the RF tuned circuit is not the usual parallel-resonant one but is series resonant. If I remember my theory right, that lets lots of voltage appear across the 4.8 ohm coil wound on one side of the ferrite, which would induce lots of current

into the 0.3 ohm secondary wound at the other side of the ferrite. The common connection of primary and secondary is to that bias point mentioned earlier, and the other side of the secondary goes directly to the base of the RF amp (the emitter is directly grounded). There's a 10 uF 'lytic from the bias point to ground, but I don't consider the conductivity of tiny cheap 'lytics at 1 MHz to be enough to consider that side grounded for RF purposes (else I'd believe it was parallel resonant). The bias point is 47K away from the collector, which is 1K away from the 4.5V supply; other than the 365 pF tuning capacitor from primary to ground, that completes the circuit enough that you could draw it.

Unfortunately, since this represents my first foray into circuit analysis in a couple dozen years, I lack tools like an inductance meter/bridge, so can't provide good values for the ferrite antenna; the wire on both windings is the same thickness and wound as closely, so my guess would be that since the primary has to be around 240 mH, the secondary is 15 mH or so as guessed by the resistance ratios. (Meter leads taken into account when measuring.)

This is fun, and I'm remembering stuff I've long forgotten. I shoulda done this a long time ago. Tomorrow I'm going to play with that 'lytic; if my theory is correct, a 100 uF can will only change the AGC time constant, and a 1 uF tantalum should do that plus deteriorate RF performance somewhat.

> least the resulting waveforms must be kept in phase...

Not necessarily. They must be kept in phase for maximum detector output,
but as long as they don't end up 90 degrees out of phase there will be
some output, reduced in amplitude but (theoretically) unchanged in quality.
It does seem there would be some phase difference in the QST circuit, as
the carrier goes through a whole lot more circuitry than the signal by
the time both reach U2 (the quasi-sync demodulator); yet we have at least
one person confirming that it works nicely.

Howdy Keith....What I've used quite successfully which is easy to get ahold of, is a pair of 3 terminal regulators in series...the one on the output or battery side is set up in CONSTANT CURRENT mode and could be anything you have at hand such as a 5 volt unit - set values to provide the charging CURRENT you desire.....The input 3 terminal regulator is set up in CONSTANT VOLTAGE mode and is set up to provide a voltage 2 volts HIGHER than the sum of your desired switch off voltage AND the VOLTAGE value of the constant current regulator....For example...if you wanted 9V switch off, and had used a 5volt regulator for the constant current unit....set this point to 9+5+2 = 16volts. You could use a 7816 regulator for the input or use a LM317T adjustable unit and have a preset pot for this point. What happens is that the regulator in constant current mode will only pass current until the DIFFERENCE voltage across it is less than 2 volts (shut down)...so as your battery comes up to that point it is charged at constant current then will NOT charge further. Your input unregulated supply to the VOLTAGE section will of course be capable of 2-3 volts above the value of this section and not exceed 30-35volts max. This cct I cooked up seems to work WELL for me - No special stuff required.

This is a little scary. The LM regulators have very wide spec ranges for
what happens when you have insufficient headroom. Varies considerably
between manufacturers and load and temperature. You could get more control
by putting the current limit in the top section and the voltage control in
the bottom
section. You'd have to check to make sure that the bottom regulator folds
up
cleanly when you limit it's input current. I've used that successfully with
discrete
regulators where I could keep some voltage on the op-amps to make sure
everything stayed regulating. But I still didn't try to quick charge
batteries with
such a scheme.

Bottom line is that if you're using low current like C/10 you can do just as
well with a
light bulb limiter. If you're trying to quick charge, this is a good way to
blow something up.

SFDR is not the same as phase noise, so what you will see is: Inside
the loop you will have the phase noise from the DDS (eventullay worse
due to multiplication) and outside the loop you will have the nose
from the VCO. Tye spurs will show up if passed though the LPF and be
equally stronger if multipication occures.

Not qutie sure what happens with phase noise and reduced clock rate,
but the -135 sounds like a good number for the digital ckts so you
would problably gain a few dB only but get much worse spurs!

>- Finally, the trick would be to lock a VCO on the same frequency as the DDS,

Yes and No, you wil have improvements inside the loop but it will be
very hard to get the close-in phase noise of the VCO to be as good as
you need. Usually one is forced to use rather large bw as to match the
VCO noise and the DDS.

I guess in your case it's up to you, spurs or phase noise which is
worst for you and then optimize the design.
One or two descrete spurs would not be that bad, especilally if they
are some 70 dB supressed or more. By carfully choosing the
centerfrequency and clock rate you shoul be able to get the spurs very
low.

Cheers.

The configuration where the collector and base are tied together
used to be known as the 'super-diode' configuration. It's not
simply a defective transistor posing as a diode, but rather a
transistor acting as diode but with lower dynamic on-resistance.

As the super-diode is forward biased, near the base-emitter
turn-on potential, it starts to draw a little bit of collector
current as well. If the collector were to go into saturation,
the base would be starved of current, and the super-diode would be
non-conducitong again. Thus the dynamic resistance of the
configuration is about a factor of beta lower than the dynamic
resistance of the base-emitter juntion alone.

If you send me the values of the S-parameters (inparticularly S11
and S22) I can calculate the necessary input and output matching
networks for you. Using single (or double if required) stubs on
standard glassfibre microstrip networks.

That may be because the RF is getting back into the osc.

> Plus you need a frequency counter to set the frequency in the first
> place, and most beginners haven't got one.

It's pointless to use a counter to set the freq on something that isn't
going to stay there for more than a few minutes. It's just as easy to
set the freq to correspond with the dial on a FM tuner.

Tom

Using a 130 foot longwire and a good crystal set design, I have
been able to drive an old Manhatten Electric horn speaker while
listening to WTIC (50kW, 30 miles away). The volume is extremely
low, but the audio is understandable in a quiet room.

For sale or trade:
If you know what these are you want them!!

I am open to offers.

Pair of good looking UHF Motorola HT100's in great shape, presently on 451 MHz.

Batteries are NG you can probably re-load them with cellular battery cells, or have one of the battery rebuilders work on them. Maybe you can put NIMH cells in!

These are in pretty good condition suitable for the Motorola collector.

And, they actually work!!! You will want to recrystal for your favorite ham freq as these are on two different repeater pairs and do not have simplex. But they do transmit and receive quite well. The insides look very good. No parts have been changed, no torn foil or corrosion.

Oh they also have the tiny factory PL board. PL 5A

Will throw into the deal some Motorola tune up adaptors for HT220 VHF, HT220 UHF and HT100 UHF

Or maybe we can trade for something else??

Sure, that's the problem, because the doc. states that the SFDR, which
I assume to be the ratio of the carrier over the worst spur level, over
a 50 kHz BW is - 70 dBc.

That means I can never achieve a better phase noise if I set my loop
bandwidth at 50 kHz.

> Not qutie sure what happens with phase noise and reduced clock rate,
> but the -135 sounds like a good number for the digital ckts so you
> would problably gain a few dB only but get much worse spurs!

Why ? I read that the spurs were, besides folding phenomena, caused mainly
by glitches at the output of the DAC. The less frequent DAC transitions are,
the less the spurs become, no ?

> I guess in your case it's up to you, spurs or phase noise which is
> worst for you and then optimize the design.
> One or two descrete spurs would not be that bad, especilally if they
> are some 70 dB supressed or more. By carfully choosing the
> centerfrequency and clock rate you shoul be able to get the spurs very
> low.

I'll think over it again. Some interesting circuit used a DDS to offset
the VCO frequency, something like this :

```
REF ---> [ Phase comparator ] ---> [ LPF ] ----> [ VCO ] ---+---->
^ |
| |
+---- [ BPF ] <-- [ MIXER ] <-------------+
^
|
[ DDS ]
```

The I.F. frequency, output by the mixer and filtered by the BPF, which can be
a crystal filter or any kind of high-Q filter, could clean-up the signal.

Cheers,
Vince

Message-ID: <36026670.83019027@news.erols.com>
Source record: 78958

My DX-390 was zapped by the dreaded "static cling." No kidding! I was folding laundry! I went in and replaced the front end FET with an MPF-102 and it works fine. Felt good about fixing it myself. Wasn't that difficult. Go for it!

While we are on the subject, does anyone remember the mod for preventing the DX-390 from muting while the main tuning dial is being turned? You have to go in and cut one wire, but I can't remember which one. This is a very useful mod for the rx.

Helical filters might be a better approach. Toko sell small ones but
their insertion loss versus bandwidth may not be as good as could be
needed. Homebrew versions can be made using raw PCB material soldered
together to make the screens.
The best design source is Zverev, but I think there's a bit in the ARRL
handbook.

> The other sort of filter which works well against pager crud is the band

> Tee them in the line between the antenna and the radio. (Simple coax
> stubs can be used too, see the ARRL Handbook.)
>

The co-ax stub is so easy to rig up to try, that I'd suggest it as a
first stab at the problem. The lower the loss of the co-ax, the sharper
and deeper the notch. Another trick, not widely known, is to use a
longer co-ax and use an overtone resonance for a sharper notch.

I remember helical resonator info being in both the ARRL handbook
and the RSGB VHF-UHF handbook, but I can't remember if it's still in the
latest editions (a re-written new edition of the RSGB book went out a
year ago) The VHF-UHF handbook has a somewhat different bias to the old
version, accepting that most people buy rather than build VHF radios.
There is a less well known RSGB VHF-UHF DX book
(by Ian White G3SEK) that carries the flag for the serious homebrewer
building a contest quality station - who wants to go beyond the
limitations of what can be bought off the shelf. There's a lot in both
the ARRL and RSGB books, at least that's my excuse for why a

contributing author to both doesn't have the contents of both in his head ;-)

Cheers
David GM4ZNX

2650. The problem with free running VCO oscillator kits ....

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-18 00:00:00 UTC
From: web_surf@hotmail.com
Message-ID: <6ttoi9$n3u$1@nnrp1.dejanews.com>
Source record: 78961
Cross-posted to: alt.radio.pirate,rec.radio.amateur.homebrew,sci.electronics.design,rec.radio.amateur.equipment

.... is that there is no money for kit manufacturers in them.

If you were a kit manufacturer, what would you rather do ?

A) Make a 1W free running VCO kit costing 15 pounds of parts and sell it for 27

Sell it to a few hobbyists

B) Make a LCD PLL kit costing 40 pounds of parts and sell it for 90 ???

Sell it to hobbyists, professionals, serious Pirates, OEM into other solutions.

Somehow I like the seat-of-the pants, understandable approach of the free-running Oscillator. It uses technology that is comprehensible to most hobbyists and beginners. It is much more cost effective for the 0.5W-10W crowd that likes to experiment with Radio. It allows more people to try their hand at kit construction and learn the basics. It has a smaller knowledge-hill that you have to cross before you feel like making your first transmitter.

The biggest issue with free running VCO designs is that they drift in frequency. Why ??

The oscillation frequency is largely determined by a LC or LC and Varactor circuit, but there is a transistor needed in the oscillator stage that contributes some components in frequency determination.

This transistor has internal capacitances and resistances which also form part of the circuit that determines the oscillation frequency. Infact the internal capacitances are such that they have to be seriously considered at VHF frequencies and upwards, creating less of a problem at lower frequencies.

Also, the input impedance of the next stage after the oscillator also contributes a bit of capacitance into the frequency determining circuit.

Lets look at why there are changes in these internal capacitances, making the VCO drift. -

i) Temperature of the transistor.
Best thing you can do here seems to be wait a bit till thermal stability is reached.

But on the other hand there are two things one could do -

i.i) Use a modern Microwave transistor (still only around 2-3 $ a pop) that is useable into the GigaHertz. They have such small internal capacitances

anyway that when they change, the delta is so small as compared to the main C in the LC circuit, that you have very little freq drift created due to temperature stability.

Look at the circuit of the BF900 dual gate Microwave FET Oscillator made popular by Eric Van Gorkum. He still swears that it had the least drift he ever saw in a free runner, making the PLL a bit unncessary for pirate operation. (FRN hosts Eric's complete dia with commentary.)

The Pulz says that is the most stable Free runner he ever built. He has the circuit at his site as well.

Fantasy Radio Holland is using that circuit and say it is good enough to drive their 300W RF Amp.

(Links to all above sites are at my links page)

So question : Why are kit manufacturers not using such modern parts in their designs ?

i.ii) Use a frequency doubler or multiple frequency doubler stages. The idea is simple, use an oscillator that runs at 1/2 frequency to the main carrier frequency needed. It will need larger LC values to resonate at the lower frequency. By comparison, the internal capacitances of the transistor will now be much smaller, leading to much lesser effect of changes in the internal capacitances.

Double the Oscillator's frequency using a frequency doubler to get the original frequency you wanted.

Veronic@ needs to be commended for their 1w and 5W free running VCO designs. They seem to be the only ones trying to build semi-decent kits for this technology. The Frequency Doubler design gives it much more frequency stability than Smart Kit's equivalent 4Watter where the oscillator is running at the fundamental frequency.

So why are other kit manufacturers not using this well-understood technology ?

ii) Voltage and current across the oscillator transistor.
Here it is important to use a voltage regulator IC to feed the complete Oscillator stage, not just the Varactor.

Why do the Veronic@ and Sm@rtkit free running oscillator kits not have a Voltage regulator for the Oscillator ? It costs only a Pound !!

This is specially surprising in the Veronic@ 1W free runner, where there is a 78L05, but it is used to feed only the Varactor, when it could have easily been used to stabilise the Oscillator transistors as well.

iii) changes in Antenna load, changing the load impedance seen by the last stage, changing its input impedance (but thats the load impedance seen by the stage before it), changing the input impedance of the stage before it.... till there is a change in the load on the Oscillator.

Obviously then one should adjust the frequency of a free runner only after the correct permanent antenna has been connencted. If you change the antenna, the circuit will run at a different frequency with the new antenna.

But 1 or 2 buffer stages after the oscillator and before the power RF stages would isolate the Oscillator to a very large degree.

The Veronic@ 1W PLL and the 1W free runner use almost identical Oscillator stages with the frequency doubler. But why, oh why, do they not use the same buffer stages of the PLL on the Free runner ? It would have added a Pound to their cost of parts only, but made the freerunner kit drastically better.

In the last 4 months, there have been 4 new PLL kits released. When did you last hear of a new Free running VCO Exciter kit ?

So it looks like free running VCOs are being purposefully ignored. Is it because if the Free running started functionally equalling the PLL in frequency stability (Not stability down to digital precision, but functionally the same meaning less drift than that which makes receiver re-tuning mandatory) then less pirates / hobbyists would buy the more money making PLL kits ??????

If all kits/circuits available were higher technology / harder to comprehend / more costly, would tend to discourage rank beginners to get into the field and experiment, eventually contributing to fewer Electronic Engineers in the world. Even propogating the myth that circuits need to be very complex before they are functionally useable will have the same effect.

My Challenge to kit manufacturers : Redesign the Free running VCO kits you have to reflect modern parts and designs available now, while still remaining in the same price range.

Antique Electronic Supply (http://www/tubesandmore.com) also has some books on this topic. I have a copy of "Radios That Work for Free" around here somewheres and I seem to recall that the author claims that his sets produce audio that can be heard from across the room (I haven't built one myself, but it makes interesting reading).

A good way to mount equipment in a rack when the equipment is not designed for rack mounting is to buy a rack drawer. Mount the radio in the drawer using its mobile mounting bracket (or something locally fabricated). Cut out the drawer front to snugly expose the radio front panel. When the drawer is closed, you have what looks to be a panel mounted radio, but you can slide the drawer out to access the radio for service, or to change its cabling.

Rack drawers, and ball bearing slides, are available from rack manufacturers, or can often be found surplus. This is a more expensive approach than bending up a set of ears to directly panel mount the radio, but it gives the radio better support, and makes servicing easier.

[well thought out and written information snipped]

> My Challenge to kit manufacturers : Redesign the Free running VCO kits you
> have to reflect modern parts and designs available now, while still remaining
> in the same price range.

Well, for many decades, the designers of tube receivers used oscillators
that were stable because they had to be. There were only two tubes in
the FM tuner, and the tuner had to work in an environment that changed
greatly in temperature because of the tubes themselves. So designers
used components that had temperature coefficients that compensated for
the temp change. And you can tell a good tube FM tuner. Not only does
the dial have that feel, but once you set it to a station, it STAYS
THERE. It doesn't drift.

Today's design attitude is to throw technology at the problem. People
would rather use a PLL and microcontroller than a few special parts like
negative tempco capacitors.
This also makes the design hard to steal because the uC has a program
that can be protected from being read.

I don't think many builders are going to want to spend the time
programming a uC and getting it debugged to control the PLL properly.
They want to get on the air. So the VFO will be around as long as there

are people who roll their own FM TXes.

And good VFO designs made with the proper components will always have
their place in FM TXes.

Thanks for the info.

2660. How lossy is your twin feeder ?

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-18 00:00:00 UTC
From: Reg Edwards <G4fgq.Regp@btinternet.com>
Message-ID: <01bde360$99bce160$67ebabc3@default>
Source record: 78971

Find out by using computer program -

################ RJELINE2.exe ################

Brand new and original. And its free !

Runs under Dos/Windows operating systems and Dos emulators.

For whoever takes balanced-pair transmission lines seriously, from amateurs accustomed to quantitative thinking, to teachers and professionals, from power frequencies up to UHF, this computer program is a "must".

Input data is requested and output data is presented in a form appropriate to radio amateurs and the HF bands. Exact, classical, transmission line formulae are used throughout at all frequencies.

For several purposes the program replaces the good old faithful Smith Chart. But its faster, more accurate and reliable, especially at the lower frequencies than the Smith Chart, which, as useful as it is, involves approximations. If you prefer, use your Smith Chart to put you in the right street and then use the program to tidy up.

For any practical twin line, from 75 to 600 or more ohms (the user begins by selecting or designing it), for any load impedance, at any frequency, the program computes line input impedance in terms of R + jX and angle. Amongst other applications, therefore, it can be used to design transmission-line impedance matching sections.

Although computed results include such values as VSWR and reflection coefficients, capacitance, inductance, the most important characteristic of any transmission line is the percentage of input power dissipated in the line for a given terminating impedance. The program directly computes line-loss, as a percentage of input power and in decibels, for any complex terminating impedance between a short and open circuit. It will be observed that minimum line loss does not always coincide with minimum VSWR.

A similar program for coaxial feeders is being considered.

Not zipped-up. Downloads from my website in a few seconds. Can be run immediately. Comments and suggestions welcome.

The component values for an elliptic lowpass filter are derived
from the"elliptic integral" which is defined as follows:

Kv=(integral from 0 to pi/2) [d(theta)/sqrt(1-(k sin theta)^2)]

The exact values are somewhat difficult to calculate and are best
found from numerous filter Tables. There are computer algorithms
worked that help with this.

Regarding question number one, I purchased one about six months ago at Ham Radio Outlet in San Diego for about $175. It was the display model and I got a discount because of that but I was thinking that the regular price there was only about $210. This price included the AC adaptor, the carrying case, and the clip on antenna.

BTW, I am quite satisfied with it. I am a Ham and only do occasional SW listening. It seems quite sensitive, even with the built in whip antenna. Not terribly selective or with a lot of dynamic range but more than adequate for the price.

I've tried the vectron site without success. Does anyone know what the
pinout might be?
It's got thru-hole pins, in two rows on the bottom of a square metal
case (soldered shut).

The pins are spaced like this

p p <-- this pin is directly connected to the metal
case.

p

p p

All the other pins are clearly insulated from the enclosure. It
measures around 2"x2".

The frequency is 8.192 MHz, fwiw, but I don't have the part number
here.

Even speculation would be appreciated at this point!

thanks,
ncc KB1DEJ

==========

More to the point, if you don't mount the kit in a decent metal
case it will drift a lot when the PCB is moved around.

Plus you need a frequency counter to set the frequency in the first
place, and most beginners haven't got one.

I'm not at all anti-VFO, but, let's face it, technology has come
a long way, and got a lot cheaper, in the last 15 years.
In this day and age, it really does make a lot more sense to
use the PLL.

Martin.

Well, sure, you can drive it, but can you _hear_ the output?? ;-)
Seriously, though, to optimize things you'd of course want an
efficient speaker (efficient at turning electrical energy into
sound energy: high sensitivity rating), and you'd want to be
careful to match impedances. The detector will have some load
impedance into which it will deliver the most _power_. That
will, I believe, depend on signal level, but it's probably going
to be in the lots-of-kohms region, unless the signal is really
big. So...you might want to couple the detector to the speaker
through a tube-type audio output transformer and see how that
does. You probably also want to play with the impedance
transformation from antenna to detector diode: try adjusting the
antenna coupling to the tuning tank and/or the point that the
diode taps onto the tank.

(There's an HP applications note on "zero bias video detectors"
or "zero bias detector diodes" or something like that which gives
some insight into optimal load impedance for a simple diode
detector.)

2672. log-per impedance and lpcad

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-19 00:00:00 UTC
From: "Franck E." <moumoug@cybercom.fr>
Message-ID: <6tv3hp$161$3@jaydee.iway.fr>
Source record: 78885
Cross-posted to: alt.ham-radio.vhf-uhf,fr.rec.radio,fr.sci.electronique,rec.radio.amateur,rec.radio.amateur.antenna,rec.radio.amateur.homebrew,sci.electronics.design,sci.engr.television.advanced,sci.physics.electromag

Follow up to rec.radio.amateur.antenna,

I have been using lpcad to design log-periodic antennas in the UHF range.

The lpcad program is fine for computing the elements and spacing.

For the impedance it always answers " optimum boom impedance is 200 ohms",
whatever the other design parameters including elements diameter.

From the photos of professional log-periodic antennas in the VHF / UHF
range, they always use a 50 ohm boom: two square tubings very close
together. This makes more sense for me than a 200 ohm boom if you want
to connect a 50 ohm coax.

200 ohms is OK for the HF bands with a 4:1 balun/transformer.

I only have an old (1977) ARRL antenna book, and I think the formula
giving the impedance of a log-periodic antennas is not accurate either.

Peter Rhodes also states in this book that "tilting the elements toward
the apex will increase gain 3 to 5 dB". How come no professional antenna
makers had the idea to simply bend the elements to take advantage of this
huge increase in gain?

I would appreciate the right formula for the impedance, or a freeware
able to compute accurately the impedance.

Thanks & 73.

F6BOM

Salut,

For 10 USD i bought Puff from Caltech, a CAD wich comes with a printed
manual, and also the EE153 course on microwave circuit.

Puff neat old AT-vintage program can draw hybrids, couplers, etc., and
help you get the right line widths for transmission lines.

It's real fun to play with, you enter scatering parameters and you
get the transparent mask on your printer to make your PCB.

Note that for preamps series tuning give more stable designs than
parrallel tuning (stubs)

> Cheers,
> Vince

Neat circuit, but it may have problems locking. There are a couple
of failure modes.

Assuming you use a phase/frequency detector, it will tend to drive
the VCO to the high frequency limit whenever the difference
frequency after the mixer is outside the bandpass filter.

You would want to put a low-pass filter after the mixer for initial
lock, then switch to the BPF when the loop is settled.

This creates a new problem. Say the normal operation was to have the
REF at 10 MHz, the DDS at 100 MHz, and the desired VCO frequency at
110 MHz.

Increasing the VCO frequency would cause the phase comparator to
lower the VCO frequency, so stable lock would be achieved.

However, if the VCO ever got to 90 MHz, the phase comparator would
try to drive it to the low frequency limit, since a lower VCO
frequency would increase the output frequency from the mixer.

The signal would then fall out of the BPF, and the loop would try to
drive the VCO to the high limit. When the signal reappeared in the
BPF, the loop would try to drive it to the low limit. The loop could
oscillate in this manner and never achieve lock.

Another problem: A free-running VCO can have poor phase noise. The VCO noise outside the bandwidth of the BPF is not affected by the loop.

You could fix the locking problems and end up with the same VCO noise performance.

Eliminate the mixer and BPF and drive the phase comparator with the DDS. Set the LPF to one-half the bandwidth of the crystal filter.

Spurs from the DDS outside the loop bandwidth would be attenuated by the loop rolloff. Spurs inside the loop bandwidth would be passed on the same as the above circuit.

Best Regards,

Mike

I would think long and hard before I bought either one. The drawback is the motorized bandswitch. They don't make them anymore. Some may be available somewhere, but I don't know for sure. It's a good radio but if that motor switch goes you are in trouble. Myself I would go for a slightly newer Icom if that is the brand you want. The 740,745,730,735,751,etc are all older models that don't have this problem. I use a 730 in the car. It's a good rig.MK

Being you have fired the tubes with no problems they should be ok. I
hadn't heard of a problem much using tubes that have been laying
dormant. More the filter caps in the power supply. These should
generally be brought up slow if have been sitting a long time. But
actually most times really doesn't matter. If it's fires up and doesn't
blow up it's usually ok. Just let em cook in a few hours at least to
burn test the whole amp.
Once fired up and stable , I'd start using it. I doubt you will have
much problems unless the caps are really dryed out. You may have to
change these after you run it a while,weeks,months, if you start showing
some ripple. Not sure if you have an oil filled or computer stack. I
have a 2k classic that has the stack. I'm thinking of changing to a big
oil filled maybe. I have a tad bit of ripple on mine and about due for
new caps. MK

First Taker opted out.--I've added a few pieces to the package to make
the decision easier. same price. I want to sell this as a package if
possible.

For Sale: A fairly nice selection of components for a CCS 813 amplifier

consisting of the Following:

2 each NIB RCA 813 tubes, serial numbers match the boxes

2 each Johnson ceramic tube sockets for 813s

1 each New 10volt at 10 amp CT fil xfmer, vertical shell mount,
Stancor P-6461

1 each 2 Pole 12 position Ceramic Band Switch Many KV insulation
like new removed from HV test set

1 each Jennings 465 Pf at 5Kv/10KV vacuum variable, 1/4 inch shaft,
very
compact and nice condx, Jennings part number
USLS-465-5D579

1 each James Millen turns counter with crank handle

2 each Ratheon 2" diameter knobs for band switch and load controls

1 each OEM linear 12Vdc/2 amp power supply for realy controls etc

1 each 1/2" X 7" Ferrite core (Amidon) for fil choke.

1 each 4 section closed space variable cap for loading in excellent
condition, 500 pf per section, ceramic insulation, built
like tank
1/4 inch shaft

2 each Porcelain shaft couplers 1/4 inch shaft

6 each 1/2 inch ceramic slug tuned coil forms for pi input network
GG

2 each 500 pf/20kv Cermic Door Knob coupling caps

1 each Alumitronics 195-1 plate tank assembly 80-10 meters, used but
styrene in good shape. Will need added inductor for 160
meter and
will include separate section of new coil stock for that
band

2 each Matching Simpson panel meters, square design kind of like S line
meters only next size up, 500 MA and 300 Ma internally shunted

1 each 54 Ufd/3500 volt Oil cap

4 ea 6X 1N5408 3 amp/ 1kv diodes on 4 ceramic turret terminal assemblies

2. each KRP style relays, 12VDC coils, DPDT contacts (10 amps each contact)
NEW with mating flat mounting octal sockets with screw terminals NEW

2 each Amperite 30 second thermal timer relays N/O 115VAC fil. NIB

2 each open frame relays for t/r switching, good insulation and modified
for RF work, 12VDC coils

1 each 4" muffin fan 115vac, quiet bearing, like new

1 each Cloned BW-800 plate choke--not checked on WARC bands or 160

2 each SO-239 connectors

2 each N type chassis mount (if you prefer N)

2 each 1750 volt/270 MA ccs plate transformers with 115/220 primary with FWB and the oil cap noted the unit will send out
around 2250 volts
or more at 400 ma all day long to the 813s.

I'll include copies of 813 amplifier designs from various sources including input network design information for gg tuned circuits etc.

The package as noted $275 plus UPS ground on around 70 lbs from my zip 95827. take off $100 and about 50 lbs if you don't want the plate transformers and the oil cap. I want to keep the rest of the package together if possible.

tnx for the read es 73

Most textbooks, (all?), describe AM modulation as consisting of a carrier that varies in amplitude. However, in the frequency domain, the carrier is shown as unvarying. Now the carrier either varies or it does not. How do you explain this apparent paradox?

> not. How do you explain this apparent paradox?

If you had a receiver/scope that was narrow enough to view only the carrier and not the sidebands you would indeed see an unvarying carrier. However, when you widen the receiver bandwidth enough to take in the sidebands as well then the three signals add in such a way as to give you the "normal" AM varying-carrier look. It's only because at that point you're not looking at the carrier, but at the carrier and the sidebands together.

73,
Mike, KK6GM

I have a Varian 5 to 6 kw 10ghz CW Klystron for sale. I can no
longer
afford to purchase supplies for building a power supply. It was tuned
at
the factory at six discrete passbands at the below center frequencies.
Included will also be the 22 page Acceptance Test Data Sheets,
operating instructions and test results. (Freq. response vs bandwidth
for
each band)

Band 1 10301.7 Mhz
Band 2 10343.3 Mhz
Band 3 10385.0 Mhz
Band 4 10422.5 Mhz
Band 5 10326.7 Mhz
Band 6 10410.0 Mhz

Bandwidth 25 MHz

It is worth over $8,000 new, but this is somewhat used. and I will
sell for
$1,850.... (or best reasonable offer plus shipping from Honolulu to
your
address) I would like to get it off my workbench and out somewhere
where
it can be put to better use. I have a 2 meter dish, but this unit
needs a
bigger and better antenna.
I will include the 2 focusing magnets, (large and heavy). Buyer
pays shipping. Estimated weight is about 250 lbs for both magnets (2
ea)
and tube. Don't be shy in making an offer.

Anyone for EME? (moon bounce) or is it possible to bounce off Mars?

I will scan a data sheet, a small picture and E-mail it to anyone who
is
seriously interested.

Regards
Ray

Hi all

I'm about to have a go at building the Norcal Sierra as described in the 98 ARRL handbook but have run into one or two problems.

Can anyone out there answer the following :

1. What are the values of C34, C79 and C80?
2. Is there a PCB layout available.
3. Is the diode in the VFO (D9) really desirable - looks to me like it will degrade the phase noise figure.
4. Is the Wilderness radio kit much different from the handbook?

thanks ... David (VK3DGN)

Yes, 100 pound for a PLL is actually a pretty nice deal now as compared to prices of yesteryear.

But the point I am trying to make is that if you had a good free running VFO kit available at approx 30 pounds, and suppose that doubled the number of hobbyists dabbling with electronics, It definitely is worth it.

What pains me is that it is very possible to have quite a decent VFO within that price range, but kit manufacturers seem to be ignoring the low price range kits, in favour of money making kits.

I am definitely not saying "Down with PLL", only saying - "Use appropriate technology". The small time hobbyists and small pirate should have access to a good VFO kit to begin with. Veronic@ comes close, but with 2-3pounds more of buffer and low capacitance transistors, they can be superlative.

So what i would love to see is this :

A 30 pound VFO kit that has voltage regulator, low capacitance transistor based oscillator, frequency doubler, 2 buffer stages, 1-2W output, negligible

drift.

Thats the challenge.

2696. Directional Coupler Theory ?

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-20 00:00:00 UTC
From: David Snyder Hale <david@isi9.mtwilson.edu>
Message-ID: <6u2hkc$5u1$1@agate.berkeley.edu>
Source record: 78909

In the Feb97 issue of QST, Bill, KA2WFJ, describes a stripline
directional coupler for VHF-UHF. Can anyone refer me to
literature sources which describe the theory of operation?

The ARRL Handbook describes full-carrier AM as an emission in which
the sidebands vary in amplitude and the carrier doesn't.

Has anyone hooked up a VHF/UHF amateur radio transceiver in an airplane
using the intercom audio?
I have a Terra COM installed in my airplane and would like to add an
ICOM 3200 but use the regular aircraft headset and boom mike.
Any ideas or references please?

I'll have to disagree with the ARRL. Yes the carrier
does vary, in amplitude,
but at an audio rate, up to 20,000 times a second. So you you are
not going to see it. On a scope you can, and you can see on negative
audio peaks where the carrier comes close to being cut off, and on positive
peaks the carrier twice the unmodulated value. You will noticed on an
s meter when a well modulated AM signal is running more than 100 percent
modulation, in the poisitve direction, the S meter will increase, on peaks.

An interesting philosophical question, is the carrier infinite small?
that is does it really occupy bandwith? How narrow can a carrier
be?? can it be infinite small. hahahha

We amateurs know different, lots of wide carriers out there :)))

2703. scanner-computer interface

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-20 00:00:00 UTC
From: zebra_z@my-dejanews.com
Message-ID: <6u3v70vma1@nnrp1.dejanews.com>
Source record: 78916

/*scan.cpp for PLL2002 scanner like RS/PRO-2033, PRO-2030 etc. This program will allow you to connect your DUMB scanner to your computer. Yes, it works with even the dumbest scanners like PRO-2033 10 channel 50 $ scanner. And will allow you to get complete control of the scanners frequency ranges and bands. For now, it only works with the scanners which use PLL2002 PLL chip, and, this includes about 90% of all scanners made by radioshack.

This interface can be used like a no parts, no restrictions very low cost all scanner interface which will allow you q00% control of your scanner.

You will need atleast the following interface between the computers parallel port
and the scanners internal circuitry: -

DB25 pins direction PLL2002/scanner Pin2 (D0)
IN ------- pin9 on PLL2002 (disconnect the PLL2002 pins from the scanners UP) Pin3 (D1) IN ------- pin10 on PLL2002 (disconnect the PLL2002 pins from the scanners UP) Pin4 (D2) IN ------- pin11 on PLL2002 (disconnect the PLL2002 pins from the scanners UP) pin6 (D4) IN ------- pullup power, connect a 10 K resistor between pin 6 and pin 13 of the db25 pin7 (d5) IN ------- VHF frontend-select (disconnect this control pins from the scanners UP) pin8 (d6) IN ------- UHF frontend select (disconnect this control pins from the scanners UP) pin9 (d7) IN ------- 800 Mhz frontend select (disconnect this control pins from the scanners UP)

pin13 (s4) OUT ------- squelch output, connect a 10 K resistor between pin 6 and pin 13 of the db25

It is very highly recommended that all these signals into the scanner be buffered by 74LS244
and those signals out of the scanner be buffered by a NPN transistor like 2N3904

As alaways, be very-very careful to not fry your scanners circuitry and LSI chips like PLL2002 etc.

PLL2002 control protocol (reverse engineered from CRO waveforms and logic analyzer dumps) The PLL 2002 has two registers:- R register= This divides the RefOsc to generate the Ref freq which is 4.1666/5 /10 /15 Khz typically This value sets the basic PLL step size N register= This divides the VCO to generate the signal to be compared against the Ref Freq. The value, in conjuction with R sets the frequency the scanner is tuned to.

The PLL2002 uses the 3 wire protocol to load values into these registers:- Pin 9 = clock, this is toggled from low - hi-lo to shift one bit into internal registers pin 10= data, this holds the bit value to be toggled into internal registers with the clock as above pin11= Enable or LE, this toggled

```
lo-hi-lo to COMPLETE the transfer of the data packet. Toggling this signals
the PLL2002 to load the R or N register

R packet 16 bits MSB first hold the R Value, 1 Control Bit always signal
that it is a R packet, then LE is toggled to complete this pkt

N packet
24 bits, MSB first, the first 8 (dummy)bits are always low, the next 8 bits
hold the N value, the a 0 control bit signals pkt completion

In fact writing the following string to the LPT1 by copy
<file-containing-string> lpt1
programs the PLL2002 to 162550 (Q:WHY ?)

001001001001001023201001001001001023201001001001001023204000100102320100102320
010010232232232010232232010232010010010010232010010010040

usage

scan > scan.001 // scans VHF band from 137 to 174 MHZ and logs
frequencies found into scan.001
scan 162550 // loads frequency into scanner
scan R N // raw mode, allows U to experiment by setting
different step sizes etc etc etc.

Use bprland C++ 3.0 etc to compile this program by Bcc scan.cpp.

This program is intended ONLY for educational purposes. blah blah blah.....

/*scan.cpp for PLL2002 scanner like RS/PRO-2033, PRO-2030 etc. This program will allow you to connect your DUMB scanner to your computer. Yes, it works with even the dumbest scanners like PRO-2033 10 channel 50 $ scanner. And will allow you to get complete control of the scanners frequency ranges and bands. For now, it only works with the scanners which use PLL2002 PLL chip, and, this includes about 90% of all scanners made by radioshack.

This interface can be used like a no parts, no restrictions very low cost all scanner interface which will allow you q00% control of your scanner.

You will need atleast the following interface between the computers parallel port and the scanners internal circuitry: -

DB25 pins direction PLL2002/scanner Pin2 (D0) IN ------- pin9 on PLL2002 (disconnect the PLL2002 pins from the scanners UP) Pin3 (D1) IN ------- pin10 on PLL2002 (disconnect the PLL2002 pins from the scanners UP) Pin4 (D2) IN ------- pin11 on PLL2002 (disconnect the PLL2002 pins from the scanners UP) pin6 (D4) IN ------- pullup power, connect a 10 K resistor between pin 6 and pin 13 of the db25 pin7 (d5) IN ------- VHF frontend-select (disconnect this control pins from the scanners UP) pin8 (d6) IN ------- UHF frontend select (disconnect this control pins from the scanners UP) pin9 (d7) IN ------- 800 Mhz frontend select (disconnect this control pins from the scanners UP)

pin13 (s4) OUT ------- squelch output, connect a 10 K resistor between pin 6 and pin 13 of the db25

pins 18-25 ground ------- connect 1or two of these to scanner ground

It is very highly recommended that all these signals into the scanner be buffered by 74LS244 and those signals out of the scanner be buffered by a NPN transistor like 2N3904

As alaways, be very-very careful to not fry your scanners circuitry and LSI chips like PLL2002 etc.

PLL2002 control protocol (reverse engineered from CRO waveforms and logic analyzer dumps) The PLL 2002 has two registers:- R register= This divides the RefOsc to generate the Ref freq which is 4.1666/5 /10 /15 Khz typically This value sets the basic PLL step size N register= This divides the VCO to generate the signal to be compared against the Ref Freq. The value, in conjuction with R sets the frequency the scanner is tuned to.

The PLL2002 uses the 3 wire protocol to load values into these registers:- Pin 9 = clock, this is toggled from low - hi-lo to shift one bit into internal registers pin 10= data, this holds the bit value to be toggled into internal registers with the clock as above pin11= Enable or LE, this toggled

```
lo-hi-lo to COMPLETE the transfer of the data packet. Toggling this signals
the PLL2002 to load the R or N register

R packet 16 bits MSB first hold the R Value, 1 Control Bit always signal
that it is a R packet, then LE is toggled to complete this pkt

N packet 24 bits, MSB first, the first 8 (dummy)bits are always low, the
next 8 bits hold the N value, the a 0 control bit signals pkt completion

In fact writing the following string to the LPT1 by copy
<file-containing-string> lpt1 programs the PLL2002 to 162550 (Q:WHY ?)
00100100100100102320100100100100102320100100100100102320400010010232010010232
01001001023223223201023223201023201001001001023201001001040

usage

scan > scan.001 // scans VHF band from 137 to 174 MHZ and logs
frequencies found into scan.001 scan 162550 // loads frequency into
scanner scan R N // raw mode, allows U to experiment by setting
different step sizes etc etc etc.

Use borland C++ 3.0 etc to compile this program by Bcc scan.cpp.

This program is intended ONLY for educational purposes. blah blah blah.....

To maintain the exact color as the VFO filter you could use some of the original blue filter material for the meter as well. Drake sells it on line at:
http://www.rldrake.com/tech/parts/partshtml/partslist.html

Do a search on the word "blue".

2708. Looking for designer of HT-220 freq synthesizer

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-20 00:00:00 UTC
From: Mike Wright <nospam@me.bums>
Message-ID: <360555E2.3733@me.bums>
Source record: 78921
Cross-posted to: rec.radio.amateur.misc,rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.amateur.doorstop

I am looking for the author of a frequency synthesizer who designed this option that can be added to a HT-220. It can select both TX and RX frequency in the 2-meter band with 5 KHz separation. His name is Dale Heatherington, WA4DSY. I have a copy of his design and I want to add it to my HT-220 page. Anyone that knows how to reach him, please let me know. [yes, I know, but I don't have a ham directory].

Thanks,

Mike
mfKILLwright@batSPAMnet.com
(remove the words "KILL SPAM" before sending message)

I have also updated the HT-220 page which also shows some photos of the inside of a HT-220. See http://www.batnet.com/mfwright/HT220.html

Another good explanation. The "vector sum" concept
should take away the mystery.

From: bc289@scn.org
Message-ID: <EzLMyw.Gt9@scn.org>
Source record: 78927

a long time ago there was an rtty tuning display construction
project, I think in Wayne Greens rag 73. It used leds or
led bargrapghs as the readout and, as I remember, plls as
the "detectors" or filters.

I'd like to get a hold of a copy of that article. I think
it was from the early 80's.

any help???

tnks es 73

> music.

I received an unexpected lesson about ASCAP when assistant manager of a restaurant in the early '80's. I had made a bunch of tapes of music at home and pateched them into the background music system (to replace the horrific muzak the restaurant chain supplied).

One day a woman customer sitting alone struck up a conversation and then asked where the music came from. I explained what I had done and she then explained to me that she worked for ASCAP and that if we wanted to continue to use the music we had to pay a fee to ASCAP. She further explained that since I had clearly not known this and that we had only been doing it for a brief time that she would not refer us to the system for legal action and likely large fines! (A very nice lady!) :-)

She explained that ASCAP represents the rightful royalty rights of the artists who created the music. Fair enough. We live in a capitalistic system, not a communal one, thus we all have an equal right to market the products of our labors at whatever price we set. Those
who take and profit from our labors without payment to us have stolen from us.

2716. Solid state relay advice ??

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-20 00:00:00 UTC
From: sca00135@mail.wvnet.EDU
Message-ID: <003d01bde481$179692e0$255e4781@default>
Source record: 78929

Hello and thanks for reading,

My daddy always told me there was no such thing as a stupid question so here goes. Can anyone give me a short primer in the operation and use of solid state relays?? I have a SS relay that has 4 terminals with the input terminals showing "3-32 VDC ". I am assuming this means relay closure upon presence of between 3 to 32 volts DC. The output terminals show "120 VAC-5 amps". I am assuming the relay will switch 5 amps at 120 VAC. My problem is, unlike a conventional relay, I do not see DC continuity between the output terminals when appropriate input voltage is applied. Do the SS relays "close" in the same manner as conventional relays or do I need a load present before closure or what?? Can I use this SS relay to switch ground or a DC voltage?? Also, what would be the output capacity of the relay at 12 volts AC. 120VAC at 5 amps = 600VA; 12VAC at 50 amps=600VA. Will this relay handle 50 amps at 12VAC????

Thanks guys and 73, Sam--K8WVA--

Hmm, I guess one way would be to filter your DDS with a BPF and let it
be the referece. Use a more "optimized" LPF as the loop filter. The
only major draw back as I see it is really you get slightly non-linear
frequency steps. This is the methode recommendet by Qualcomm in their
very good application notes for their Q3032 PLL chip.

Reducing the speed would reduce the jitter and hence the phase-noise.
But I try to recall an article in Ham radio years ago and I think the
ratio between clock freq and phase noise was not as simple as in a
PLL.

Clocking with high speed compared to the wanted output frerquecy will
ease up on your filtering, reducing the problems with folding at fs/2.

Check old Ham Radio Magzine from mid -80s
Sorry cannot find my copies....
But there is an article about wide-band VCOs using coax-cables i the
resontant ckt.

It also have a basic program that will let you optimize the lenght of
the cable and the caps around it.

If you can't find the article let us know and I will do a more
extensive serach in my "library".....

Cheers

On a scope you're seeing the sum of the carrier and the upper and
lower sidebands. Yes, they do sum to zero instantaneously at 100%
modulation. No, the carrier itself does not vary.

I would recommend that you report this problem to your ISP or the
news service you are using. I see about 100, or more, postings a day.

I read the news groups through "http://www.dejanews.com". It seems to
work good, and it's a free service. You can get a nice spam filtered
email drop, as well.

Greetings:
Over the weekend I was given two 12 volt 12 amp hour gell cell batteries which would be great for mountain top QRP work.

Neither battery had been charged recently but indicated 12.6 volts +/- when tested with a multimeter. I don't have a charger for these batteries and was wondering what voltage, amperage and charge rate is ideal for a cell of this type. Any guidance is greatly appreciated!

>Any ideas or references please?

My suggestion is that you have an avionics shop add the jacks to your
intercom system for use with external audio equipment. This will keep
the permanent part of your installation legal (form 337 and all that
nonsense). You should power your radio from the cigarette lighter
plug, or from batteries.

It helps if both your radio and the intercom use a line (600 ohm)
interface for the audio link. However, if it doesn't, you can always
connect a resistive divider across the speaker leads to load it down
and prevent it from overloading the mic input of the other side.

Once this is set up with easily accessible jacks in the cockpit, you
can plug in any portable radio, tape recorder, or cd player you want
in the aircraft and you should be in the clear with your friendly
neighborhood FAA inspector. You'll have to key your radio
independently of the intercom system, of course.

One last note (this should be obvious to most pilots): Do not use the
radio while flying on an instrument flight plan in instrument
conditions. Both hobbies (aviation and ham radio) will fare poorly
from the publicity resulting from a near miss or (heaven forbid) a
crash.

This is sad, but I can't remember. Sometime last year or early this year I'd say.

How did you find out? People were talking aboutit here at the time, and there was an ARRL bulletin in rec.radio.amateur.misc about it too.

I finally picked up the September issue of QST yesterday (that's sad too, that I don't buy the ham magazines as soon as they hit the newsstand, like I once did) for the followup article by Wes Hayward on his Spectrum Analyzer. On page 52, there's a bit about the winners of the "ARRL Doug DeMaw. W1FB, Technical Excellence Award", which was previously called the "ARRL Technical Excellence Award". I think it's a fitting renaming. Doug DeMaw was a constant in QST while I was growing up.

I see the bit in QST mentions that he died last year.

I have two roller inductors. Both Porcelin. One is a very large unit capable of handling very large power. The roller is 9.5" long and 3.5" wide, it has about 80 turns of wire. The contact rides on a glass rod. Very smooth turning, and in excellent condition. It will handle from broadcast band all the way up past 30MHz. This would be great for a large amp or a large antenna tuner. $185 shipped.
The second Roller is much smaller but equally the same quality. The roller measures 4" long by 2" wide with 24 turns of wire. This would be great for a smaller tuner or transmitter up to a KW+. $75. Both these roller inductors are in excellent shape. I just changed my mind on the project I was working on. 73 Chris VE3NGW/W4 Florida

I still had the announcement in my email file.

Here it is

73's
David
W4IDX

ZCZC AG57
QST de W1AW
ARRL Bulletin 57 ARLB057
From ARRL Headquarters
Newington CT September 29, 1997
To all radio amateurs

SB QST ARL ARLB057
ARLB057 Doug DeMaw, W1FB, SK

Acclaimed ham radio icon Milton F. ''Doug'' DeMaw, W1FB, died September 28. He was 71. One of the most widely published technical writers in Amateur Radio, DeMaw was diagnosed with leukemia earlier this year and had been in failing health in recent weeks.

DeMaw was first licensed in 1950 as W8HHS. An electrical engineer, he was a member of the ARRL Headquarters staff for 18 years--from 1965 to 1983--and served as Technical Department Manager and Senior Technical Editor from 1970 to 1983. During his tenure at HQ, DeMaw served as editor of The ARRL Handbook. In 1970, he engineered the shift in emphasis toward solid-state design in QST and the Handbook. He has hundreds of articles in QST and other publications to his credit. DeMaw also was founder and publisher of VHFer Magazine. (His wife, Jean, W1CKK, also worked on the Headquarters staff.) DeMaw was a life member of the ARRL and a senior member of the IEEE.

After retiring to the family farm in Luther, Michigan, he was elected chairman of the Lake County Board of Commissioners and continued to write books and articles. He also tried his hand in the Amateur Radio business as proprietor of Oak Hills Research. Among his other books, DeMaw wrote W1FB's Design Notebook, W1FB's QRP Notebook, W1FB's Antenna Notebook, and The ARRL Electronics Data Book, which remain popular. In recent years, DeMaw also penned a regular column for CQ magazine.

A former ARRL colleague, Membership Services Manager Chuck Hutchinson, K8CH, counted DeMaw among his friends. ''Doug loved to experiment with circuits and antennas. He also loved to encourage others to try their hand at building,'' he recalled. Hutchinson said

DeMaw not only wrote prolifically about ham radio but also about gardening, another of his avocations. ''He was an avid gardener and cook,'' he said. DeMaw also was an outdoorsman and hunter. ''He loved to hunt with bow and rifle--both modern and muzzle loader. He was very good at throwing a knife or hatchet,'' Hutchinson said. Paul Pagel, N1FB, also was one DeMaw's colleagues during his days at ARRL HQ. ''Amateur Radio benefited greatly from his work,'' Pagel said. ''He was a multifaceted man. I doubt there was anything he couldn't do if he set his mind to it.'' Jerry Hall, K1TD, who also worked with DeMaw during his years at HQ, called DeMaw a writer of ''uncanny'' ability. ''Doug could write it once, and it was done,'' he recalled.

Survivors include DeMaw's wife, Jean, and a son, David, N8HLE, a technical writer who lives in Connecticut.

I have a big problem with the conventional saying that "the AM carrier itself does not vary."

Think about how an AM plate modulator works. It raises and lowers the plate (collector, drain, whatever) voltage at an audio rate. When the modulating signal is silent, the plate transformer (pass transistor, whatever) acts as a simple DC choke (resistor) to maintain the carrier at its average amplitude value. Otherwise, in the presence of a modulating signal, the energy available to the final PA stage varies at the modulated rate. The PA's job is to amplify the fixed-frequency carrier signal. Hence, the amplitude of the carrier does vary on an instantaneous basis. This instantaneous variation is what gives rise to the existence of the sidebands, which are what ultimately carry the 'intelligence' of the modulated signal.

You can't see it vary on a spectrum analyzer, because if you narrow the RBW enough to separate the sidebands from the carrier, you'll have to lower the sweep rate to the point at which you'll be displaying the *average*, not instantaneous, carrier amplitude. It may be mathematically impossible to *observe* the carrier's amplitude variations, but a look at the schematic of any AM transmitter will reveal that there are two ways of looking at the problem. You can look

at it as a constant carrier plus two sidebands, or you can look at it as an infinitely-narrow carrier being amplitude-modulated. Information theory decries the latter point of view, but there's no escaping the fact that the signal was generated in exactly that way in the first place.

First see how good the state of charge is. Connect each battery to an auto headlamp or some other good load and see if the voltage holds up (better than 11.5 would be nice).

If each battery can power a load without too much voltage sag and you have a variable power supply, connect them (one at a time) to the supply at about 13.2 Volts. Decrease the voltage if necessary to keep the current under one Amp. The current should slowly (an hour or so) decrease to 200 mA or so. If it doesn't, cut back the voltage a little.

If a battery needs more charge (big voltage sag), use basically the same procedure, but let it run at 1.5 to 2 A for a while before cutting back.

Once you have a good charge in the battery, you can leave it on a 12.8 to 13.2 V supply almost indefinitely, as long as the current stays below a couple of hundred mA.

: carrier.

Alright, something for nothing! So if you have 100% modulation, the
voltage on the PA is zero, but out of this narrow filter you're still
getting the same carrier power out for zero power in - right?

Stephen

However, when you widen the receiver bandwidth enough to take
: in the sidebands as well then the three signals add in such a way as to
: give you the "normal" AM varying-carrier look. It's only because at

You will never see anyone in the U.S. take you up on that. No one can
legally sell that high a power without exporting it to another country.
It would have to be FCC type accepted.

Be careful when using a variable supply to charge a battery. I have
now burned up two different supplies by conecting the supply set at a low
voltage to a higher voltage battery. The reverse current destroyed
an output transistor. I now (finaly) use a protective diode between the supply
and the battery.

I would suggest a charger that limits charging current to about 200 ma until the terminal voltage gets to 13.6 - 13.8 volts. They should float there fully charged with no problem. The main thing, I think, is to limit the initial charging current at low voltage to keep from heating the electrolyte and venting gas.

The carrier doesn't vary in amplitude, and any text which says it does
is incorrect. The sidebands vary in amplitude with varying modulation.
The *vector sum* of the carrier and sidebands thus varies with modulation.
So if you observe the signal in a wide enough bandwidth in the time domain,
say with a scope, all you see is the vector sum, and it varies in amplitude.
That's what an envelope detector sees too.

But if you tune through an AM signal with a sideband receiver, you'll hear
the constant carrier as a hetrodyne tone of unvarying amplitude. And if you
observe it on a spectrum analyzer, you'll see the constant amplitude carrier
with a varying sideband on each side of it. That's because both methods
can resolve the various frequency components of the vector sum and show
them to you.

Bill, why?

An amp based on 813's in grounded grid is a classic ham amp.
Sounds like a good HAM project. How may CB'ers do you know
that would even know what and 813 IS, much less how to build
an amp kit themselves. (Yes I know a few, but still....)

This seems like a legit HAM ad, not one aimed at CB'ers.
30L1's 30S1's, ALPHA 87's what have you are all linear amps.
Says so right on the lable. Do you suggest than folks selling them
go to rec.radio.cb too????

Sorry to foam at the mouth, but Bob is just a ham selling off some
extra parts.

KE5FX wrote:

>I have a big problem with the conventional saying that "the AM carrier
>itself does not vary."

(Adding to the reply I just posted...)

It's just the same as if you connect an audio transformer secondary (which
delivers 12 volts peak, 24 volts peak-to-peak) in series with a 12 volt
battery,
off to a load. If you look at the instantaneous voltage across the load,
you'll
see that it varies between 0 volts and 24 volts. What is the DC voltage
delivered to the load? I'd say that it's 12 volts, independent of what the
audio transformer is doing. If you really believe that an inductance (the
transformer secondary) is a DC short, then you'd have to say that, too.
The _instantaneous_ voltage on the load can be zero, but the _DC_
voltage must always be the battery voltage.

Similarly with the RF coming from the AM transmitter: the _instantaneous_
RF power (and RF voltage and RF current) can be zero, but the
carrier power remains constant.

Just as we resolve the signal to the load in the first case into AC and
DC components, we resolve the AM signal into sideband and carrier
components. In both cases, the total signal is the composite of the
two components, and in both cases, we can talk about instantaneous
values of the composite. But we should be careful to distinguish
between the instantaneous values of the composite and the values
of the (frequency domain) components making up the composite.
Both ways of looking at it are useful, and both are correct. Proper
use of terminology keeps all that straight and avoids argument.

(For the nitpickers, which I can sometimes be, technically, anything that's
truely DC must have been there since the beginning of time and will
continue to exist forever, but in practice it's useful to think in terms with a

rather shorter timespan...)

Cheers,
Tom

> 73, Sam--K8WVA--

Sam OM,

You need to be more specific about your application. Do you want to
actually switch a KW 'hot', or merely switch when there is no RF
applied?
Assuming the latter, a fairly small relay can handle the job. The
current will
be, for 1KW at 50 ohms impedance, solving from P=(I^2)*R, I=4.5 amps.
Solving for the voltage from P=V^2/R, V=224V RMS. So all you need is
a relay the can CARRY 4.5A, and have insulation good for 224V RMS (which
is
316V peak), assuming a 50 ohms system. If your applicationis for HF
only
(<30 MHz), I think that any reasonably careful layout in the relay box
will
work just fine.
If you find you have to switch hot, then a vacuum relay is probably
called
for.

Right... the whole question is all about nitpicking. :)

Assume you have a signal generator whose output amplitude is being modulated by a 0.01 Hz sine-wave signal. You can say, "I have a constant-frequency signal (carrier) which is varying in strength over a period of a minute or so," to which the AM-purists will have to respond, "No, you don't. You have a constant-amplitude carrier with sidebands at 0.01 Hz. Give me a filter with a 0.01 Hz passband, and I'll prove it to you."

At that point, if you accept THEIR view of things without question, you have essentially given up the right to own a CW signal source whose amplitude can be varied over any length of time... at all!

> voltage on the PA is zero, but out of this narrow filter you're still
> getting the same carrier power out for zero power in - right?
>
> Stephen

The brief answer is *yes*. When you turn the power off to the PA then
you're *modulating* the PA. If you turn it back on in 5 minutes then
you've modulated it with a signal in the mHz (no, not MHz -- mHz)
range. If you reduce your observing bandwidth below that then you will
indeed see a steady carrier; otherwise you will see the sum of the
carrier and the sidebands and that's the zero signal you see. There's
nothing gimicky about this -- when you modulate your carrier with a mHz
or uHz signal (by pulling the plug for the night) then if you want to
view only the carrier and not the carrier+sidebands then you *must*
narrow your observation bandwidth to mHz or uHz. Whether that's
practical or not doesn't matter to the mathematics -- the trigonometric
identities don't suddenly break down below 20Hz.

What's an AM-purist anyway? The sensible view will depend on what the hardware is capable of -- since none of our receivers have 0.01Hz passbands it probably doesn't help much to talk about separating these sidebands from the carrier, but the mathematics hasn't suddenly divided by zero or otherwise gone south. BTW, I maintain that a CW signal is FM... :)

> That may be because the RF is getting back into the osc.

No, most often it is because capacitance of the track coming
from the top of the tuned circuit (amongst others) is changing
as the PCB is moved around. Half freq. VFO's don't 'pull',
yet they must be mounted in a metal case for reasonable stability.

_If_ getting within 25kHz is 'good enough'. I don't think that it
is in these days of digitally tuned radios. In some cases you need to
be within 10kHz on the fringes, or the radio mutes.

Martin.

I got my 4 MRF150's as part of a kit with a pre-drilled and etched board. The old ARRL Handbook used to have a 4x300 Watt amp project, with a board layout, if you need the layout form and dimensions, there is an excellent diagram at the end of the .pdf document if you have Adobe Acrobat reader "acroread" ..... http://www.mot.com/SPS/WIRELESS/documentation/mosfets.html and click on MRF150.

So the carrier is by definition unmodulated.

Modulation is the process of modifying a carrier to have it carry information.
If the carrier is unmodified it is unmodulated.

I can see what you're saying, but it requires a new definition of the word
"modulate".

I wonder if the tables are archived anywhere. Over the years I've used one I found in an old Short Wave Magazine. I'd hoped to write some C source to automate the look-up and calculation, but I never got time and these days don't build very much anyway. I did write a program that accepted the values I put in from the table and give the capacitor values and number of turns I needed on the cores, having given it details of the core and wire size -- I somehow lost that in disk upgrades.

2760. Need Source for Icom HT DC power plug

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-22 00:00:00 UTC
From: qsy220@aol.com
Message-ID: <19980922173637.03768.00000239@ng-fd2.aol.com>
Source record: 78799

This looks like a standard coaxial DC power connector except there is a small male pin inside the hole in the plug. This is the same plug that is used on the Icom BC-77A wall charger and CP-13 cig. lighter cable that are used with the IC-W2A, IC-2SRA, IC-4SRA, etc. The plug barrel measures about 0.198 in (5 mm) in diameter and is about 3/8 in (9 to 10 mm) long.

Need a source for these plugs. Please reply via email.

Thanks, Bill.

CCI, 508 Millstone Drive, Beavercreek, Ohio 45434-5840 also stock HF amp kits, but don't supply filters etc., they have an excellent Kit, EB-104 which supplies 600W from 6 W input using 4x MRF150 FET's, needing only 50V at 15 Amps, much easier to build than the 12V stuff which uses tons of amps and 100W input, you lose much more in heat than you use in signal.
Hmmmm..... I've got to complete mine sometime soon, just need to build the filters, mount it all and I'm off. I've got a filter kit from the URL above (rfelect.htm), but it looks pretty mickey mouse against the ellipticals I designed and have the bits for.

Logic says it should, but it's an active device and possibly there is a current limitation. I've a number of them around for quite a while, but have never braved using them. Perhaps the later ones are better, back in the 70's the company I worked for used some (not sure of manufacturer) and they used to go bang in spectacular fashion, usually at switch-on time, though there was never any collateral damage except for the awful smell and mess. The ones I have are something like 220 Volt at 20 Amps, so I thought perhaps using them at 13.8V and similar amperage might be OK, so I've kept them. The ones I have were acquired at ham rallies.

: FM... :)

Mike! I think you've been listening to too much chirpy CW! ;-)

It seems to me that you have two choices: you can let the semantics
rule your world, or you can realize that we're just trying to describe
a signal, and although our descriptions might be rather different in
the time domain or the frequency domain, or different still in some
other domain (e.g., sampled-time), the signal we are describing is
still the same signal. Just because I accept that the carrier is
invariant doesn't mean I have any trouble at all with sending "CW",
which really isn't CW. In fact, "unmodulated" beacons aren't even CW,
in that there is always noise associated with any real signal.
Like Mike wrote, it's not all that hard to take a sensible view of it
all and get on with things.

(With not very much work, I could look at sidebands less than 0.001Hz
from the carrier. Can many of you generate a signal clean enough to
make it worth my effort to do so? Since my LO would be a little noisy
itself, I probably couldn't resolve very much amplitude that close in,
but it would be worth a go.) (A lot of ;-)s here!)

When you generate an SSB signal, what are you modulating?? ;-)

sigh.

OK, solid state relays are NOT really relays in the true sense of the word, they just act like relays under some circumstances. The reason you see no DC continuity is that there are no contacts to close. The device which does the switching is a triac, which is kinda like back-to-back SCR's in parallel, with (usually) some switching circuitry to "close" the relay at zero crossing of the AC signal. This is really nice if you want to cut down on switching noise on your AC lines.

Triacs & SCR's basically have a nearly infinite resistance until their gate is given an appropriate signal, often around 10V. Then they go into conduction and get a very low resistance. There's usually a minimum voltage drop of a few volts across the junctions, which, depending on what you are using to measure continuity, may be why you see no "connection".

First your DC question. In general, the only way to turn OFF a triac (or SCR for that matter) is to stop the current flow through it with no gate signal applied. With AC this happens at every zero crossing. It won't happen with DC. So, you'll likely get a switch which will be OFF until you apply the 3 - 32 V signal, then it'll be ON forever, until you turn off the current elsewhere in the circuit.

Now, you are right in assuming it is rated for switching 5A at 120VAC. It will probably switch 5A at other lower voltages as well. It's not uncommon to derive the gate voltage from the voltage you are switching (remember, it's often around 10V), so you might not be able to get too far from the rated voltage either. It probably won't handle much more than 5A though. It's not a good idea to push the current limitations through silicon devices.

A good book on this is Motorola's Thyristor Device Data book. I don't know where you can get one though. Some electronics parts stores have or can get the books. You could try contacting your local Motorola sales office, but they might not want to talk to individuals. Or see if you can order the book (or if it's on-line) from Motorola's website at http://www.design-net.com

Well, that's the whole point I'm making. You can set the freq with the
counter all you want, but no sooner than you finish setting it than it
starts to drift and soon will be off freq. So I don't see why someone
would go to all the trouble to get a freq counter to adjust it, and then
have to keep adjusting it very often.

It's easier and quicker to set the receiver to the wanted channel, tune
the VFO to the top and bottom of the channel where the receiver loses
the lock on the signal, and then set the VFO halfway between these
points. Or use a regular analog receiver with the AFC disabled.

ANd remember that the above assumes you have a cheapo VFO. If the VFO
is well designed and built and is stable, then it won't drift and the
counter method will work okay, and it'll stay on freq for a much longer
time.

W9JUC 10 Meter activity today

Aside from pipeline into ZS, land the last few days it was a pleasant surprise to here and work the following stations on my HOMEBREW DELTA LOOP ANTENNA.today.

South and West Africa were active until 1615Z at this QTH (near Chicago IL)

1627Z IZ8BRI Egi Southern Italy S9
1630Z Z31JA Venco East Macedonia S5
1640Z G0XAM /mm Les near Sicily S5
1644Z TK5PB Bruno Corsica S7
1744Z IK6SNR LU Central Italy S9+5
1745Z IZ6CLZ ANTHONY Central S6
1746Z IZ6BJL ALEX near ROME S9+5
1755Z IK5SRF PAULO Livorno S8
1806Z EA7HBP SALVA SPAIN S9+

New Zealand and Australia made their daily appearance begining at 2200Z.

Nothing heard out of The Far East or Central
Asia today on 10 meters.

Unfortunately I was unable to monitor 10 meters all day today but as Scarlet said," Tomorrow is another day".

You can view my TEN METER DELTA LOOP ARRAY at

2773. AM modulation

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-22 00:00:00 UTC
From: Alfred Lorona <w6wqc@juno.com>
Message-ID: <360885D5.7DCA@juno.com>
Source record: 78812

The consensus thus far appears to support the frequency domain view of an AM radio freqeuncy carrier where the time domain representation is a composite of a constant amplitude carrier and sidebands.

Tom Bruhns correctly stated that we are trying to describe the same signal but that our descriptions are different in the two domains. This is precisely the problem. Our explanations are contradictory and ambiguous. My orignal posting was intended to act as stimulus to see how far we can go in order to resolve the problem.

Nothwistanding the consensus so far, the signal is still generated in time and we should find suitable description of it in both domains that do not appear contradictory; explanations that avoid all embarrassing questions when passing from one to the other.

For example: assume an ideal Class C AM 100 watt amplifier modulated with a v-e-r-y low frequendcy. In this ideal amplifier the plate voltage will swing from twice the DC voltage to zero voltage. Do you say that during the relatively long time interval during which the plate voltage is essentially zero that 100 watts of carrier power is streaming out of the tube in accordance with the frequency domain explanation?

Krauss, Bostian and Raab in 'Solid State Radio Engineering' pose the question in similar fashion when they write ".... AM can be gnerated .... by placing the modulating voltage in series with the collector voltage of a Class C RF amplifier that is driven into saturation. When the modulating voltage is positive, the amplifier receives a higher collector voltage and delivers a correspondingly GREATER output signal; when the modulating voltage is negative, the collector voltage and the amplifer output are SMALLER than their unmodulated values." Caps are mine.

We know that swinging the plate voltage below zero, in the negative direction, results in over-modulation and CARRIER CUTOFF. Are we to say that as soon as the voltage returns to zero, the carrier suddenly jumps to the 100 watt level? Or are we to say that the carrier is a very low value and increases as the plate voltage increases? How do we answer that one?

In U. Rohde's new book "Microwave & wireless synthesizers"
the design process is covered in detail. (J. Wiley & sons)
Maybe it's in the old edition, too.

Don't expect wonders from 3 mm semi rigid coax.

Steve:

I found and saved this when I was trying to learn about gell cells, hope it helps!

73, DavidC AA1FA

Gell cells need to be charged as follows: Apply a maximum of 2.4V per cell (6 cells in a 12V battery = 14.4V) and the charge current must be limited to
battery capacity divided by 5. That's 8 amps for a 40 AH battery. You really
need an adjustable voltage/adjustable current limiting power supply. Charge
the battery until the current drops to about 100-300mA for a 40 AH battery. Disconnect the battery from the charger when charging is complete.

Alternately you can "float" charge these batteries which means leaving the battery across the charger. You can do this for the life of the battery if you want which is about 5 years. To float charge, reduce the voltage to 2.25
to 2.3 volts per cell. Float charging is often used in battery back-up systems to instantly switch to the battery if the power supply fails.

Over charging is one of the few ways you can damage a gell cell.

Gell cells should be charged at least once every six months. If the battery sits
around too long a chemical process occurs in the battery that causes it to be
unable to charge to full capacity. This is why it is a bad idea to buy those
"new" batteries at the flea market. Generally they are unsold batteries that

sat on the shelf too long and are now for sale cheap at the flea market.

You cannot over-discharge a gell cell. They are not subject to cell reversal
like some batteries. They also do not have the "memory" effect like some Ni-Cads.

>type. Any guidance is greatly appreciated!

They are lead acid batteries, of course, and the fully charged terminal
voltage after they sit a few hours should be 12.6 volts, so they appear
to be in good shape. (Immediately off the charger they'll read 13.8 volts,
but that "surface charge" quickly dissipates and they drop to their normal
full charge voltage of 12.6 volts.)

Lead acid batteries are normally charged with a *constant voltage*
charger. This will be in the range of 14.2-14.8 volts depending on
a number of factors. But gell cells can't take as rapid a charge as
most wet cell batteries, so you need to current limit the charger.
A current limit of about 10% of the battery's amp-hr rating is
considered appropriate. So current limit the charger to 1.2 amps.

A variable bench supply with current limiting can be pressed into
service to charge this sort of battery. I use my Motorola service
supply for this often. I set the terminal voltage to 14.2 volts no
load and set the current limit to 1.2 amps. At beginning of charge
of a discharged battery, the current limiter keeps the current at
a safe value, and later in the charge cycle, the constant voltage
regulation gives the desired taper charge to top off the battery.

You can build a suitable supply to dedicate to battery charging
using most any circuit that offers current limiting. The venerable
723 regulator chip supports this sort of operation.

>It would have to be FCC type accepted.

FWIW, there's a fair chance the FCC will legalize microbroadcasting at
this kind of power level later this year. At that point, there would
probably be a market (not a huge one, but probably a profitable one)
for such a device in the U.S.. My understanding is that this kind of
thing is already legal in several other countries (probably including
Canada and the U.K.) so there could certainly be a market elsewhere.

It would indeed (probably) have to be type accepted, and it may not be
possible to legally market such a thing in kit form. (then again,
Heath and other companies did legally market commercial-service
type-accepted two-way gear in the 1970s)

I'd say that using micro-coax below 500 MHz would not give optimum
phase noise, but it sure makes a very mechanical stable oscillator.
So for those not striving for the *very* best noise performance, why
not give the coax resonator a try??

Cheers

and when restoring an old set you might possibly change the electrolytic
capacitors to some higher value because the low value types used earlier
are not as easy to obtain as larger, but 'modern' types, so it is
perhaps not important to have something near the earlier inductance

The main point I am asking for is frequency stability against changes in Antenna, Temperature and Antenna. Power is secondary in the Exciter.

BTW, Kit manufacturers in USA still do use tricks to be within limits --

A) Make a 1W kit and then put a T resistor pad in front to make final output FCC level. Put out the "Mod" on the Internet

B) Purposely put a useless big resistor straight after the Voltage regulator to drop the voltage being supplied to the RF stage. Leak it out to hobbyists that the resistor is supposed to be removed.

If you see some of the Commercial kit circuits on the net, the above tricks are obvious.

You could ask Alan, G3XAQ - he's recently had a big power transformer
and choke made for a power amp he's building, and was very happy with
the firm that did the job for him.

I might suggest that as the thing went open on you, there may be some
benefit in seeing if a larger part would fit. It sounds like you need a
gauge or two thicker wire, and a pre-emptive strike of getting two made
sounds attractive.
The lack of bobbin sounds like a bodge design trying to get the wire
size up without going to the next larger stamping size for the lams.

Measure the area of the window in the core, use wire tables that
include packing factors and you'll get a good estimate on the number of
turns.

Cheers

2793. Re: Solid state relay advice ??

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-22 00:00:00 UTC
From: Bob Lewis <aa4pb@erols.com>
Message-ID: <36078F24.1563D54B@erols.com>
Source record: 78876

The switching element in a typical AC solid state relay is a triac. The low voltage of your ohm meter is not enough to fire the triac so you don't read continuity like an ordinary electromechanical relay. Once a triac is conducting it wont stop until the voltage is removed therefore if you hook it to DC it will never turn off once you switch it on. AC passes thru zero volts as the polarity reverses so the triac turns off at the next crossover after you remove the control voltage. The current and voltage ratings are not directly related. Reducing the applied voltage by half does not permit the device to handle twice the current. The current is limited by the on resistance of the triac and its ability to disipate heat. The voltage rating is the maximum open circuit (off condition) voltage that can be applied without the triac breaking down.

2795. Relay for RF switching??

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-22 00:00:00 UTC
From: sca00135@mail.wvnet.EDU
Message-ID: <006701bde625$b3b676e0$375e4781@default>
Source record: 78878

Hello and thanks for reading,

I want to build an antenna switching relay box and wonder what specifications would be acceptable for the relays. I want to switch a KW. Would 10 amp contacts be acceptable?? I have looked at the relays in the Yaesu FAS-4 relay box which I believe is rated at a KW and the relays "look" rather small physically. Any advice would be greatly appreciated. Also, other than keeping the leads as short as possible, are there any other potential "pitfalls" I might expect in the box construction?? Am I likely to get an unacceptable impedance bump in the relay box?? Thanks guys and 73, Sam--K8WVA--

2796. Are U310 and J310 FETS the same part?

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-22 00:00:00 UTC
From: af389@lafn.ORG
Message-ID: <3607AF9D.DA9904F1@lafn.org>
Source record: 78879

Frequently, I see J310 FET used in Ham
RF circuit designs. Some use J310 and less frequently I see U310.

I only have U310's in my parts cabinet. My Motorola datasheet
only covers U310 FET.

A pointer to source for data sheets on Internet
for each would be helpful.

Thanks for clarification and pointers.

It seems to me the problem is in a definition of terms. Yes, when you
modulate, you control the _total_amount_ of RF which is generated.
And yes, when there is no modulation, that leaves only the carrier.

>You can't see it vary on a spectrum analyzer, because if you narrow the

>place.

Yes, indeed, a carrier which is modulated, and the modulation
produces energy at frequencies other than the carrier frequency
(so long as it's not DC modulation). The total energy in an AM
modulated wave is more than the carrier energy alone.

If you define "carrier" as the sum of all RF energy transmitted,
then you're right, the "carrier" varies. However, that's not the
accepted definition. The accepted one is that the carrier is only
the energy on the, um, carrier frequency, and that the energy in
the sidebands varies, and that the sidebands are independent of
the carrier. Indeed, they are so independent, you can transmit
information with no carrier!

Two ways of looking at the same thing. One is in the frequency domain (spectrum analyzer) and the other is in the time domain (oscilloscope).

frussle@erols.com (Jake Brodsky)
shared these priceless pearls of wisdom:

->On Sun, 20 Sep 1998 15:06:46 -0700, Karl Geng <geng@marcoisland.org>
->wrote:
->
->>Has anyone hooked up a VHF/UHF amateur radio transceiver in an airplane
->>using the intercom audio?

All the time. No big deal.

->
->My suggestion is that you have an avionics shop add the jacks to your
->intercom system for use with external audio equipment. This will keep
->the permanent part of your installation legal (form 337 and all that
->nonsense). You should power your radio from the cigarette lighter
->plug, or from batteries.

No, in the first place, a 337 (READ the title) is a MAJOR AIRFRAME
alteration. The addition of a two-way radio is generally not considered a
major installation. If the ham rig has its own breaker, at that point it
departs from the aircraft system per se. In the second place, what is all
this extra jacks stuff and why are we telling the radio shop to do it?
Find a friendly local airframe mechanic that is willing to take the time to
show you -- after all, YOU are the expert on ham radio, no?

->
->It helps if both your radio and the intercom use a line (600 ohm)
->interface for the audio link. However, if it doesn't, you can always
->connect a resistive divider across the speaker leads to load it down
->and prevent it from overloading the mic input of the other side.

No, not quite. Intercom audio links are quite generally designed to accept
anything from 4 to 1000 ohm driving impedances. This paragraph totally
confuses the poor guy.

->
->Once this is set up with easily accessible jacks in the cockpit, you
->can plug in any portable radio, tape recorder, or cd player you want
->in the aircraft and you should be in the clear with your friendly
->neighborhood FAA inspector. You'll have to key your radio
->independently of the intercom system, of course.

Why would you want to do this, with a perfectly good noise-cancelling
headset already installed in the airplane? Use as little external bushwa
as possible to do the job.

->
->One last note (this should be obvious to most pilots): Do not use the
->radio while flying on an instrument flight plan in instrument
->conditions. Both hobbies (aviation and ham radio) will fare poorly
->from the publicity resulting from a near miss or (heaven forbid) a
->crash.

Ummm...that is pretty much up to the pilot in command, isn't it? Last time I looked, the guy in the left front seat is the first one at the scene of the accident and it is up to him/her as to how to prevent that.

The short answer to the original question is that we do it all the time, but the engineering of the system isn't done over the morning coffee. The most difficult job is switching and matching mic levels from the aircraft mic into the ham radio. Other than that, it is pretty much straightforward.

> infinitely wide bandwidth, so the sidebands just sneak in and sum
> themselves with the carrier!

As a follow-up to the AM modulation thread:

In building and testing a home-brew FM generator, I had to grapple with the same mind-bending thoughts about the time and frequency domain that have been discussed in this thread. This was especially true when using the technique of nulling the carrier to establish the amount of deviation. Some of the common-sense misconceptions I had to work out:

1. A handy technique to check deviation is to increase the modulation level until the carrier is nulled. (This is dependant on the modulating frequency and the Bessel function). But how can the carrier be nulled, when I can see right on my oscilloscope that the signal is still there, unchanging in amplitude?????

2. When looking at the theoretical spectrum of a sine-wave-modulated FM carrier, there are all these discrete spectral lines. Careful use of my receiver as a spectrum analyzer verifies these lines. How can there be discrete spectral lines when the carrier is being smoothly and continuously changed in frequency???

The theory really is right, and these non-intuitive results are a result of simple intuition failing when it comes to the time-frequency domain translation.

Good thread!

On Wed, 23 Sep 1998 14:28:42 GMT, axeleng@online.no (Axel Eng) wrote:
>Do you mean that the average digital receiver DOES NOT have AFC?

That's basically correct. There is no need for AFC if the receiver can be maintained accurately on frequency, and that's what digitally tuned receivers do. They are designed to receive FM broadcast stations, and FM broadcast stations don't drift much. FM broadcasters are required by law to maintain frequency to a tolerance of less than 1 kHz, and most do a good bit better than that. That same tolerance is fairly easy to maintain with a digitally tuned receiver, so no AFC is required. AFC was necessary for analog tuned receivers due to *receiver* drift, but since that problem has been solved, and since the broadcast stations don't drift, there's no reason to add AFC circuitry to the receiver anymore.

Jim, I respect your experience. However, you should also realize that
not everyone has the ability or the authority to argue these things if
ramp checked. A radio attached to the aircraft as I suggested is less
likely to cause an FAA Inspector to get suspicious.

As seen in Avweb, pilots are already being cited for plugging a GPS
receiver in the cigarette lighter and hanging it on the yoke. (It's a
silly claim to say the least, but it was made)

I believe in the KISS principle too. I also believe in covering one's
ass in case of a ramp check by someone who woke up on the wrong side
of the bed.

Sure is. I don't know about you, but if someone is using the ham
gear, whether it's me or a passenger, I'd be concerned about my
navigation equipment raising flags in IMC. Yes, you're legally
allowed to do it. But I don't think it's a good idea.

>The short answer to the original question is that we do it all the time,

Again, Jim, I respect your experience in the matter. And in theory
I'd agree with you. However, I have opinions regarding FAA ramp
checks. I don't have the alphabet soup to back up my arguments with
an inspector, and suspect neither does Mr. Geng or he would not have
asked the question.

Put yourself in our shoes for a minute: I'm not arguing the law. I'm
suggesting a conservative approach to avoid problems on the next ramp
check.

Do you think I'm being paranoid?

When the carrier is nulled, it means that all of the power in the FM signal is in the sidebands and none is in the carrier. The sum of sideband power and carrier power is a constant value. The carrier itself always supplies all of the power that is in the sidebands. Whatever power is in the sidebands is subtracted from the carrier.

Bernd OM,

See any ARRL handbook, or engineering handbook in a library for
complete wire gauge tables. There are both British Wire Gauge and
American (U.S.) Wire Gauges (AWG), but most all references I find in ham
radio are for AWG.

> For guages larger than 0, use negative values, ie 000, use -2

A somewhat related and easy-to-remember rule of thumb: for every
increase in 3 wire gage sizes (i.e. #30 to #27), double the CMA
(circular mil area), weight (per unit length), and current capability.
Resistance (per unit length) will be halved.

If one can remember that #30 AWG has a CMA (circular mil area) of
approximately 100 (actually it's 101) and #10 AWG measures about 1 ohm
per 1000 feet and can handle 15A, one could construct a wire table from
scratch!

For some unknown reason, _some_ digital receivers do mute in the
presence of small carrier frequency erors. I suspect this is
unintended, and comes about due to the use of noise squelch
circuits which respond to the conditions on the ADJACENT as
well as the wanted channel, i.e they interpret the frequency
offset as interference which needs to be suppressed.

>
> In any case, i would not discount a good free running VCO for hobbyists just

> cares about 25-30 Km ?

The fringes can be at 100m if you are running an FM25 or somesuch.
The reason I would hesitate to popularise the VCO is that too many
hobbyists who haven't got a clue will build terrible drifting
monstrosity kits and interfere with their neighbour's radios. The
PLL is quite low cost and gets around a major source of _POSSIBLE_
interference.

Remember, if you want to become a VCO expert no-one is stopping you!!

Best Regards,

Martin.

Anyone seen plans or any available rf preamps that are just a pwb w/
parts so I can mount into an old tube radio for more gain. Need to
cover 15 and 10 with a bypass switch. I've seen Mirage but that's
for in-line w/ RF power applied. Just something cheap ....

Typical glass fibre PCB has a dielectric constant between 4 and 5.
The ARRL handbook quotes G10 board as having a dielectric constant
of 4.5.

2815. Suggestions for a 25W HF amp

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-23 00:00:00 UTC
From: l2jarvis@mindspring.com
Message-ID: <3609829f.34438223@news.mindspring.com>
Source record: 78751

Hello,

I'd like to build an amp for my recently completed 20M SSB QRP rig;
something in the neighborhood of 25W. I've found that 2 watts will do
wonders on CW, but not so for SSB!

I'm considering an MRF426 (NPN bipolar 28V, 50mW in, 25W out), but
would prefer a push/pull arrangement with two devices in a TO-220
style case case. This would require that each device dissipate about
25W each. Can a TO-220 case do that?

I'm not adverse to FETS, though I've never built a FET amp. I saw an
interesting circuit using two IRF511's, but that device is very
inefficient above about 10MHz.

Any suggestions?

Thanks, and kind regards,
Lee - KN4VN

There are three plugs of that style listed in the new RS catalog on
page 295.

Item: 273-1707 is 5.50 mm OD, 3.30 mm ID, pin is 0.9 mm
273-1719 is 5.50 mm OD, 3.80 mm ID, pin is 1.80mm
273-1721 is 6.90 mm OD, 4.20 mm ID, pin is 0.7 mm

I do not know whether any of the three will fit your specific
application.

Hope this helps.

The place to find out is the manufacturer's data sheet. I've looked at a few and seen maximum charge current limits that ranged from 25% to 40% of the capacity rating. That would be 3 A to 4.8 A for a 12 Ah battery. You can maintain this current until the battery voltage reaches about 14.5 V, then you need to switch to constant-voltage charging.

Consider the hockey puck. Viewing it in one plane shows that it is round;
in another you see that it is rectangular. Although we can recognize the
pattern we've seen before and identify the hockey puck, there is in fact
no actual way to see enough of it from one vantage point alone to verify
completely that it is a right rectangular cylinder.

> Nothwistanding the consensus so far, the signal is still generated in
> time and we should find suitable description of it in both domains that
> do not appear contradictory; explanations that avoid all embarrassing
> questions when passing from one to the other.

No one has yet contradicted my definition of modulation as modifying a
carrier to introduce information. I haven't yet learned of any method of
producing modulation or its associated sidebands without generating *and*
modifying a carrier (even when that carrier is not transmitted).

I have a feeling it will be difficult if not impossible to come up with a
definition of modulation that somehow dissociates that "constant" carrier
we see on the spectrum analyzer with the sidebands we see alongside it.
Those sidebands cannot exist without a carrier which was modulated to
produce them (again, even when the carrier is not transmitted along with
the sidebands); though they may look like separate entities, this is a
case where Fourier analysis of the signals does not actually describe
pieces which we know how to generate separately and combine later (as with,
for example, a square wave, which we can synthesize from its individual
components). You could only combine a carrier and two or more sidebands
after using some carrier to produce those sidebands; you can't obtain the
sidebands without a carrier in the way you can obtain separate sine waves
to synthesize a square wave with.

So perhaps it's time to acknowledge that we're discussing *views* of a
thing we may never actually grok in its entirety. Suggested reading:

> that one?

There is not really a contradiction here. If you want to talk about the
amplitude of a signal at a single frequency, you have to filter out any
components of the signal at all other frequencies besides the one you're

interested in. The key to unifying the two explanations is to realize that in order to observe the variation of the carrier amplitude in an AM signal, you need a filter which is narrow enough to exclude the sidebands. The only trouble is, using such a filter to observe an AM carrier will prevent you from seeing the very effect you're looking for!

If you feed a signal through a filter whose passband is 1 Hz wide, how long will it take before you see the signal appear at the output of the filter? If you remove the signal abruptly, how long will it take before the filter's output dies out? In other words, just how long does it take the filter to "recognize" that the signal is in its passband?

The answer, in both cases above, is a significant and finite amount of time, on the order of one second, depending on how you characterize the filter's exact response. That's not just "the way the filter works" -- that's the way the math works. If someone gives you a complex waveform at an unknown frequency around 1 Hz, and asks you to name the exact frequency of its fundamental component, how long do you have to watch the waveform before you can do so with certainty? The answer: at least one complete cycle, or about one second. A filter doesn't possess any psychic powers that you don't -- its response has similar time constraints.

So if you take a carrier that is being keyed on and off (i.e., amplitude-modulated 100% by a square wave) at a rate significantly faster than 1 Hz, and feed that carrier through our hypothetical filter, you can see that the output of that filter is going to remain nonzero, even when the carrier is switched off. Remember that any real-world filter will have energy-storage elements -- either inductors and capacitors, or arrayed memory elements, depending on how the filter's implemented. The presence and magnitude of those elements will ensure that the output of a filter with a 1 Hz passband cannot, by definition, turn on and off faster than 1 Hz.

If the reference you are looking at is in the US, then the numbers
refer to AWG (American Wire Gage).

A fairly accurate conversion follows:

Diameter in inches = 10^(-0.05035 * AWG_number - 0.4884)
Diameter in millimeters = 10^(-0.05035 * AWG_number + 0.9164)
For guages larger than 0, use negative values, ie 000, use -2

John's answer is dead-on. The mental block some people have is that
they conciously or unconciously think in terms of an instantaneous
picture of the "carrier" at zero at the trough of the modulation cycle.
However, taking an instantaneous picture of something implies an
infinitely wide bandwidth, so the sidebands just sneak in and sum
themselves with the carrier!

Fun thread!

> Hello,

> I have a rather simple question. In many parts lists I see wire specified by
> numbers e.g. #20, #26 etc. I assume they refer solid copper wires. How do
> they translate into diameters?

> Thanks in advance
> Bernd

The hash (#) stands for gauge. However, there are several standards,
SWG - Standard Wire Gauge, AWG - American Wire Gauge (use this one
for publications from USA) and BWG - Birmingham Wire Gauge.

Some standard examples are :-

Wire No. SWG AWG BWG

#10 3.25mm 2.59mm 3.40mm
#15 1.83mm 1.45mm 1.83mm
#20 0.92mm 0.81mm 0.89mm
#24 0.56mm 0.51mm 0.56mm
#26 0.46mm 0.40mm 0.46mm
#30 0.305mm 0.25mm 0.305mm
#35 0.203mm 0.14mm 0.127mm

Hope this helps,

Regards,
Malc G4OQR

Ok, I just bought a 50W mobile dual-band radio, and I want to
run it off of a simple UPSsystem (i.e. car battery + trickle charger).
Would a trickle charger be (relatively) easy to build, and where could
I find a schematic?

Pete.

Please help me understand this muting.

The FM bandwidth is atleast 75 Khz,

There is obviously enough signal strength 10Khz away from carrier freq

The Q of the receiver cannot be so sharp that it kicks in a muting circuit for only 10Khz off tuning. I am sure if it was that sharp, it would have bad effects of a regular station when properly tuned.

In any case, i would not discount a good free running VCO for hobbyists just because it sounds bad at the remote fringes. If it is OK for 1-3 Km , who cares about 25-30 Km ?

2837. SSB PA drive level with/without RF speech processor

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-23 00:00:00 UTC
From: LA8AK@online.no
Message-ID: <36082758.58907883@news.online.no>
Source record: 78832

Bought a 432MHz 280W FM solidstate PA (for base stations?) from Josef Wimmer OE2IWM at Weinheim VHF meeting (DL0WH). It was mentioned that for SSB one should only run it with 130W RF (when modified for linear operation).

Since I always use RF speech processor with the FT-902DM* I wonder if it is possible (theoretically) to use higher RF drive level with ssb than without processor, one doesn't have those speech peaks to pass.....?

73
Jan-Martin LA8AK

*)FT-902 is modified using 2x 1N4148 clipper and has two ssb-filters, reports says the RF clipper in my rig works ufb.

>25W each. Can a TO-220 case do that?

The 2SC1945 is rated at 20W, the emitter is connected to the heatsink tab, so you don't need any insulating hardware. A pair of these should give about 20W PEP. It is not a good idea to run the transistors in a linear amp, at close to their maximun rating. You might be better off using, higher power, stud mounted devices. A pair of transistors, designed for VHF mobile use, should be suitable for your amp. Some of the surplus suppliers on this side of the atlantic, sell VHF power transistors, at reasonable
prices.

For info on RF transistors try www.mot.com

>I'm not adverse to FETS, though I've never built a FET amp. I saw an
>interesting circuit using two IRF511's, but that device is very
>inefficient above about 10MHz.

Cheap, switching, or audio mosfets, work very well on the lower bands. The high input capacitance (about 1000pF), makes them difficult to use on the higher bands. You can get proper RF power FET's, at a price!.

Avoid using expensive devices, in a prototype amp. I have blown up more RF transistors than I care to remember Hi!.

i have a crystal converter that i built out of a magazine article. it is for listening to shortwave frequency broadcasts on an am car radio. now that all car radios are digital-display i cant get between-station frequencys. this limits many shortwave channels that dont happen to fall on even steps. my question is this....how do you "pull" the frequency of a crystal off of its regular value? if i could shift the crystal frequency then i could recieve the "in between" shortwave signals on a modern car radio. i dont remember the name of the crystal oscilator used in the circuit but it uses parallel- mode crystals. does anyone have any ideas?

Have you looked at the MRF136Y ? It has 2 push-pull FETs in
a single package. Rated for 30 watts at 28 volts however
it is in a typical ceramic package with a mounting flange.
2 watts will easily drive it to full output.
There is a sample circuit in the Mot. databook for this device.
Cheers, Hugh VA3TO

For some ideas about chargers check:

http://www.unitrode.com/apps/apps_sbj.htm#Battery Charging

Application of a chip like this would do a much better job than just a trickle charger. Depending on the battery capacity, heavy use periods could drain the batt. Not likely to happen with a charge managment circuit of sufficient capacity.

Ron,

Actually, those are the Adaptaplug series that are used with the Radio Shack "universal" AC adapters.

HOWEVER, on page 190 they do list some that are possibly correct. Look at 274-1531 through 274-1534. These look promising and follow the sizes listed on page 295 but these on page 190 are the actual plugs that you can ACTUALLY solder on the end of a cable.

Thanks for you help.

The ARRL Handbook for 1995/6/7/8/9 has an excellent 50W Project in Chapter 17, designed by an HF PA design engineer, that I think you would like.

You will find kits for preamps, transverters, and power amps for all
bands from 50 MHz thru 10 GHz.

I have the following Heath items for sale:

SB-610 monitor scope, good shape, $ 80

IB-1101 freq counter. Works great, looks great. As far as I can tell,
everything is original. Manual is included. $ 65

I have the following Heath manuals available. All are in good condition.

IO-103 Five inch scope $ 12

GR-2000 TV Set $ 12
GR-2000-6 TV Remote $ 5
GR-2050 TV Set - Five book set $ 30
GRA-2000-1 TV Clock $ 3
GRA-6001 TV Clock $ 6

Prices do not include shipping from Florida.

I've gotten a used dual port KAM that came without a manual.

Is there anyplace to download a copy of the manual?
A quick diagram of the HF and VHF radio wiring connections
would help get me going

It has version 2.72 firmware installed. Back in the deep recesses
of a dark desk drawer, I found a KAM version 3.0 chip. Any info on
what modes these old versions support?

Any information will be useful.

Thanks - Dave.

I'm assuming you are adjusting the drive for 130 watts using CW. Since the object is to keep the amp in the linear region of operation, I don't think you should try changing that part of the tune up procedure. Normally, you'd be overdriving using voice if you exceeded 140 watts CW with a good, solid 280 watts out. Don't forget that a speech processor adjusts the voice waveform so that more of it is *closer to* the peak value. Even with this, you should check if this is right for your operation, because the measured power out is dependent on supply voltage as well as your power meter calibration. If you don't have the equipment to verify the signal is clean, have someone tune above and below your signal to check for spurs.

Jerry OM,
You would use any of a number of cookbooked designs to be found in the usual sources such as Doug Demaw W1FB's QRP notebook, ARRL's solid state design, etc. A single fet or mosfet can give you 15-20 dB of gain. You can agc the amp too if you want to, but probably not worth the trouble. Just build it on a small scrap of PCB, ugly-style; its just a few components.

Frank:

There are a number of PC based programs which work rather well.
However, one of the more simple ones to set up and use is MicroSmith
done, originally, by Wes Hayward. It is available from ARRL for a VERY
nominal cost. I have loaded this program on EVERY PC and laptop I own.

QST had plans several months ago for a cheap "DC to daylight" preamp based
on an MMIC. It doesn't get much simpler than that.

2876. Re: Need Source for Icom HT DC power plug

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-24 00:00:00 UTC
From: qsy220@aol.com
Message-ID: <19980924171234.27851.00001283@ng115.aol.com>
Source record: 78784

The correct plug is available at Radio Shack and is catalog number 274-1354.

They have it mislabeled as 5.5 mm OD and 0.3 mm ID (it should be 3.3 or 3.4 mm ID) with a 1.0 mm pin. But it does seem to be the correct one. It is known as an EIAJ Class 4 plug (10.51 to 13.5 VDC.)

Thanks to all who replied with info.

What you need is a VXO. This allows you to pull the crystal several
kilohertz off its marked frequency. Depending on the oscillator circuit
you are using, building a VXO could be as simple as adding a 5-100 pF
variable capacitor and small inductor (experiment with values between 2
and about 50 uH) in series with the crystal. This is critical and
requires a fair bit of experimentation to get maximum freq shift.

Or, you may be able to build a whole new VXO instead. My webpage (URL
below) has several links to sites which have info on VXO circuits.

Really, that's pretty much it. Keep an ammeter in series, and protect
it with a fuse. (of value about equal to the meter's full-scale
reading) Bring the voltage up to maybe 10-15% of the cap's rating,
watching the current. (if it starts to climb quickly, shut it down!)
Let it sit there for a few minutes, then bring it up another 10-15%.
Repeat until you reach the cap's rated voltage. Let it sit there for
awhile. If the current stays reasonable, you're in business...

Of course, if the cap is for use in tube gear, we're talking about
lethal high voltages, so be careful!

> KD8RG

Mark OM,

If you can build a pair of 813's, you can certainly build a quad.
There is basically no
difference, right? All that happens is the input and output
capacitances double,
the plate impedance will be 1/2 that of a pair, so you will select the
output pi-net
values accordingly (assuming you are going to use a pi-net on the
output), etc.
The actual schematic, of course, will look the same, basically. "Being
done before"
is almost a certainty, but what if it hasn't? The job is no tougher
either way.
If you have the tubes on hand, and are interested in running 813's, then
there is your answer.

GL and enjoy!

Don, W6JL

Hi Jim OM,

Don't you hate those discrete-step car radios? I do. Give me
continuous tuning any day
(and with a KNOB); I want to do my own tuning, HI.
A solution: find a continuous-tuning car radio (the old ones are
excellent).
Another solution: a VCXO. In addition, you can parallel crystals of
the same frequency and
increase the "pull" beyond what one crystal will move.

>I don't have a schematic. Any ideas??

Yeah, but you won't like them, Sam. About the only practical way to troubleshoot these supplies is to individually test the components. The crazy protection circuits won't let you do conventional troubleshooting. Some of the parts can only be effectively tested by substitution, which means you need an inventory of parts for this thing to repair it economically. We chunked ours in the dumpster and replaced it with a diesel truck battery and float charger after going through that for about the tenth time.

>reach working voltage.

Yeah, but it'll probably go POW anyway. You want to vary the voltage over a period of hours from zero to rated working voltage. It sometimes works better if you bring the voltage back to zero several times in the process of working up to full working voltage. Use a current limiting resistor so if it goes POW, it won't take your supply with it.

: interference.

I guess it depends which problem you prefer, PLL/VCO putting out
a comb of regularly spaced (but very stable) sprogs, or a single drifting
output.

Producing a stable free running oscillator as a kit would be a real
challenge. Harking back to the good old days of kits, Heathkit's
transistor VFO's were shipped assembled. As a junior engineer at a major
manufacturer I personally tested many hundreds of VFOs for professional
communication rx's. Despite using the highest quality components we had to
thermal cycle, datalog frequency vs temperature, individually compensate
with a mixture of tempco caps, repeat the process until good, to get
acceptable performance.

Source record: 78716

HOw far back are you thinking? The June 1972 issue of QST had such
a converter (with details for either 6 or 2 meter output), and I'm quite
certain it was repeated in the ARRL's FM & Repeater Handbook that came out
shortly afterwards. It may have shown up in a Handbook or two. It was
a grounded gate FET feeding a 40673 MOSFET, with a bipolar transistor
oscillator/mutliplier scheme for the local oscillator.

Back in the days of "220 - Use It or Lose it" days, there were various
articles about getting on 220. CQ had a short series in the early 70's,
by Byron Kretzman, which detailed adding a converter (I think it was
tubes) to a surplus FM receiver, and then an actual conversion of a
surplus receiver directly to 220. There was an "idea article" in QST,
I think in Decmber 1971, or January 1972, with various ideas and little
detail. It mentioned the idea of a converter, and it always seemed like
the June 72 article was a followup.

Has there been something more recent? I don't recall seeing anything, but
then I haven't been keeping a good collection of the ham magazines in
recent years.

Surely you can find a 220MHz converter schematic, and then it's just
a matter of changing the output tuned circuit to 2 meters, and changing
the oscillator chain to something that feeds the mixer with 76MHz
(220-144) or so. In fact, you can probably start with any VHF converter
circuit as long as you're prepaid to rework the tuned circuits to 220MHz.

But you're talking about receivers where the tuning of the VFO has to
track with the tuning of the RF and mixer stages, complicating things.
This is not a problem with a transmitter.

Re: monstrosity kits above, well that's already happening. The Ramsey
FM-4 was a real problem for me. All the projects on the web sites seem
to be mediocre to poor in that respect.

Yes, indeed. I played with a pair of 813's and they are tough to get tuned at higher frequencies, so I imagine a quad would probably require something other than a traditional pi network to match the plate to 50 ohm loads. My power supply blew, putting the experiments to an end some years ago, but I do remember that I never actually got it tuned right on 10M. I think you can, but I dont know about 4 tubes. Somewhere, years ago, I saw something where a guy had designed a different type of output network to get around the low plate impedance, but I cant remember where or what it was or even what kind of tubes they were. I am positive that it can be done, but you'll have to do a little circuit analysis and design and of course, the fun part... experimenting. Good luck!

Source record: 78720

The ones I have restored may have been different to others, but I used a high value resistance, Then connected a supply equal to the cap's rating. If the cap is badly leaky, the voltage comes up real slow as the leakage drops. I always left em on overnite at least. I would pick resistors that would only alow a few mils even if the cap is totally shorted. I've never had one blow doing this, but I had some that wouldnt heal. I have blown some by just throwing the power supply on them, though. If someone is around that's not expecting this, they could have a heart attack. Sounds like a .357 Mag. :)

I suspect a plate to grid short in the tube. that will burn something,usually plate choke is w eakest link therefore it burns out..when you get a grid to plate short that puts hv on the grid ,grid coupling cap is 600 to 1000 v rating, when it shorts out that puts hv back into the exciter,Whamo!! I have had that happen a few times with amplifiers in the last 50 years.. find a known good tube and start over..put a 10 ohm 10 watt resistor in series with hv from power supply, that will act as a hv fuse and destroy the resistor instead of plate choke .. Good luck 73 Harold W4PQW,

Source record: 78641

You may have trouble using 4 813 s if you try to work 15 or 10 meters, interelectrode capacitance is pretty high for 4 tubes. mkes for poor L/C ratio ,poor effeciency and lots of heat and smoke.. if you stay on lower bands should be OK good luck Harold W4PQW

I am looking to buy a 10 Meter mobile radio, preferably the HR-2600, or Ranger 2950, or the radio shack rig that was on the market several years ago. The radio must be in very good to excellent condition. I also have an HTX 202 2-Meter HT that I would possibly be willing to trade for a 10 Meter radio. make me an offer if you have a 10 Meter rig you are willing to sell.

Hello all,
I need whatever info I can get regarding the above. We plan to use the above for our club rpt. The guy who brought it in a flea market inthe states said it came with no manual. We connected it to the rx
and tx units using supplied cables attached to J3 and J5 at the rear of the unit. The interface is a small black box six inches wide, 1 inch tall and 3 inches deep, with green
repeater enable led, red c.o.r. led and yellow setup led. There are only two buttons on the front one is a rpt enable and the other is a labelled "setup". Also there is a dip switch inside the unit. (Do you have any info on these
button and dip switches?) As we'd like to cross link this with another rpt we will
appreciate any info on the pin outs of J1 and J2. Hopefully this will save us from hours of poking around with a scope probe inside the unit. hihi.

Best regards from DU

Source record: 78722

It seems to me that MFJ made such a device that was designed for use with a 2M HT but it could also be used with a scanner as it was powered by internal batteries. I am certain that they made a converter to allow reception of 156-164 MHz by converting this range to 144-148 MHz in two bands (156-160 and 160-164.) I think there was also a 220 version that converted from 220 to 2M. These converters used BNC connectors so you would need the proper adapters, etc to use them with something other than a handheld scanner.

Ahhhh, I was right . . . the 1990 AES catalog shows them to be MFJ-313 (156-164) and MFJ-314 (220 to 2M.) Seems my memory IS better than Bill Clinton's!!

The Other Bill

2918. Re: Question: PVC for balun and coil forms.

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-26 00:00:00 UTC
From: Roy Lewallen <w7el@teleport.com>
Message-ID: <360C7859.A5AE9656@teleport.com>
Source record: 78723

I believe that came from an experience he had with a 160 meter antenna, loaded with a coil of relatively fine wire wound on a PVC form. When the coil melted under power, he mistakenly thought the loss was due to the PVC. It actually was due to conductor loss heating the wire to the point that it could melt the PVC. There's no problem in using PVC as a coil or balun form at HF, unless the application requires extremely high Q (such as for some mobile loading coils).

Well, all switchers aren't as bad as Lambdas. Some of them are downright easy to troubleshoot and repair. Lambda is in a class of its own when it comes to unrepairable switchers. The designer of this particular supply must have gotten some bad acid the day he designed it. The feedback paths are insane.

The only one I've ever had much luck with was the ones in the old
Apple][computers.

I have succeeded in repairing a couple of other ones by replacing
every electrolytic capacitor, and every transistor and/or diode that
tested shorted. But for every one that succeeded, there were 4 or 5
that were lost causes.....

I do have a bunch of Lambda *linear* supplies at work that work great,
and have been in service for something like 25 years without a
failure...

2923. VCO Frequency Pulling

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-26 00:00:00 UTC
From: pat@orrell.prestel.co.uk
Message-ID: <360cbc8a.319840@news.prestel.co.uk>
Source record: 78728

Hi All

I have a general VCO pulling question. Consider a VCO with a pulling figure of let say 10MHz into a vswr of 2:1, which means that the free running VCO would move by 10MHz if the load was varied over all phases

Now if some dBs of isolation is placed between the load and the VCO this 10MHz will be reduced. Is there a formula or relationship between the isolation required to reduce the frequency pull to a certain frequency (say 1MHz)

Pat@Orrell.prestel.co.uk

> The job is no tougher either way.
>If you have the tubes on hand, and are interested in running 813's, then
>there is your answer.
>
when parallelling more than two tubes it becomes more important to
measure all tube electrode connection wires to be exactly the same
length from a common point, the actual length is not so critical as that
they are equal. It is important for good efficiency even when you build
280kHz Console LW-transmitters.

meaning all grid connection wires must be eaqual,
all anode/plate connection wires to pi-filter coupling capacitor
screen connection wires length to bypass capacitor
all cathode grounding - equal length to ground

>Don

Don, et al,

The problem with 813s at the higher HFs is, as has been mentioned, the high plate capacitance. The ARRL Handbook specifies 14 pF. This is just as much a problem with one tube as it is with 2, 3 or 4.

An example:

The Handbook gives a rule of thumb for determing the resonant plate impedance for a given set of operating conditions. Assuming class AB1, the formula is

RL = Vp / (k * Ip)

where k is between 1.5 and 1.7 for AB1.

Also from the handbook, typical operation of a single 813 is with 2500 plate volts and 145 mA plate current (single tone). Plugging in the numbers and using the best case of k = 1.7, we get an RL of slightly greater than 10000 ohm.

Using additional formulae from the Handbook for calculating the values of a pi network to match 10K to 50 ohm with a practical minimum Cin of 19 pf (14 pf for the tube + 5 pf minimum for a tuning cap) shows that the tank Q must be approximately 35.

A little work with ARRL Radio Designer shows that when the pi net components have unloaded Qs of 500 for the capacitors and 200 for the inductor, the loss in the tank is about 0.3 dB or 25 watts. Most of this will be in the inductor. In addition, the tuning of this tank

will be *very* touchy and will probably drift during a transmission which will exacerbate the problem.

Now let's examine a four tube amp. Tube capacitance is 4 * 14 = 56 pF, the required RL is 10000 / 4 = 2500 ohm.

Doing the math will show that the necessary tank Q can actually be lowered to *only* 30.5 with an insertion loss of 0.25 dB resulting. This assumes the same minimum tuning capacitance of 5 pF and no additional strays due to the four tubes. Power dissipated in the tank is ~ 81 watts.

If a single band amp is built, some of the foregoing problems can be overcome, but if a band-switched design is desired, 813s should probably be limited to 20 meters and below where the capacitance problem is much more tractable.

Wes N7WS

I've heard some "Ham Lore" that there is PVC and there is ---- PVC.
The test is/was to place a small piece in a microwave oven (along
with a large glass of water as a 'dummy load') and cook it for a
minute or so. If it gets warm, you probably have ---- PVC vs. PVC. :-)

hth -- but, it just may add to the confusion...

2928. THANKS RE HIGH VALUE INDUCTORS (SMOOTHING CHOKES)

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-26 00:00:00 UTC
From: Graham Fitt <Graham.Fitt@btinternet.com>
Message-ID: <6ujdh7$d5c$1@plutonium.btinternet.com>
Source record: 78733
Cross-posted to: rec.radio.amateur.homebrew,uk.radio.amateur

Thanks to everyone who responded to my posting concerning the repair/replacement of a choke for a valve HT Supply.

I managed to find a local firm (see below) who supplied me with a former/bobbin, which
they wound with the correct wire for the inclusive sum of five pounds. I reckon this was a bargain, since to do the job myself I would have had to buy or make a former and probably buy far more wire then I will ever need. Added to which their winding machine puts on a neat winding, which means they got on more wire than I could have done by hand and it's neater as well. I reassembled the former on to the laminations myself. The firm told me that it would have cost me a lot of money for them to do that as being a one off it would have to have been done manually.

Now that the PSU is fixed I can get on with repairing the rest of the equipment!

The new winding came out at 212 ohms as against 220 ohms in the original. This was because the presence of a former meant that fewer turns could be wound on. I'm not worried about 8 ohms though. I didn't bother to measure the inductance of either choke. It will of course depend on the current, which I shalln't know until I get the equipment working and measure it

As a matter of interest the E and I laminations were not interleaved, which made the choke easy to dismantle. Apparently this is normal for chokes as opposed to transformers There was no air gap though. The choke forms part of a choke input filter. It is my understanding that air gaps are only normally used for chokes used in capacitor input filters. I could of course be wrong though.

Go to your pubic liberry and read up on "rubber crystals" and/or "crystal
rubbering" in old ham mags. You might have to go to microfilm to get it,
but it is there. You can use a simple capacitive rubber-er to "Stretch"
crystal behavior, but it was done all thetime back in the days before kids
of 40 or so started agitating tor No--Skill licenses.

Good luck.

That's a good qualitative test for how a material will perform at 1-2 GHz, but doesn't tell you much about how it'll do at HF (except that if it *doesn't* get warm, it's probably very good indeed at HF).

Wouldn't it just be simpler to build a cheap synthesized PLL type unit? I'm guessing that in the long run, most pirate radio stations would be better served by putting out a clean, stable signal that's less likely to annoy people using adjacent channels. If the pirate station doesn't cause any trouble, then the officials will have no reason to waste a lot of time tracking them down and putting them out of business. On the other hand, if the pirate uses a VFO, and it drifts, then the pirate station is begging for the officials to come and shut them down.

2940. 600w440mhz amp project 4 sale

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-27 00:00:00 UTC
From: jimmoci@aol.com
Message-ID: <19980927093337.29642.00002644@ng02.aol.com>
Source record: 78659

For sale;
Eimac CV-400 cavity amplifer. Needs High voltage and filament supplies, and case (The cavity is complete with tube). This runs an 8874 tube and will do 600 watts on ssb/cw or 300 watts in continuous duty modes. It is tuned up for 450mhz repeater use but can be tuned anywhere from 400-500 mhz. Eimac still gets a pretty penny for these things and it is still in their most recent RF amplifier spec book. I am asking $300 firm shipped cont. U.S.
Thnaks,
Jim

Dave,

Check out my article in September 1979 Ham Radio Magazine titled,
"Split-Band Speech Processor." While it isn't necessarily the
simplest that can be found it is not complicated and I can say with
all modesty (ahem) that it is the most effective outboard processor
that you can build or buy.

The split-band approach is even used in the TS-870, where there is
ample DSP power to implement something else.

73,

Wes N7WS

VCO drifts, Pirate knows he has drifted, he does something about it

PLL makes spurious signal, Pirate does not know, does nothing

Both have a place. There will always be a low end requirement for
experimenters and beginners.

Weather we like it or not, VCOs will be made by beginners, hobbysits as they
are simples to make/comprehend.

Some in this news group do not want a VCO kit as it cannot reach the levels of
perfection they want. It is not the road to technical nirvana. I agree.

There are already VCO kits out in the market. The technical purists cannot
stop that ? Infact I guess that most hobbyists are lured in by simple VCO
circuits before they migrate to other technologies. It is a great stepping
stone.

But in any endeavour, 20% of the efforts gets you 80% of the desired results.
There is many times no need to kill yourself to get that last very bit of
result as the cost parameter starts rising sharply after that point.

What I am saying is that Kit manufacturers are putting only 10% efforts into
decent design of VCO kits, leading to lousy VCO kits.

If they have a VCO kit that currently drifts 100 Khz, while PLLs drift 200-500
Hz, we all know which one is better if you have the extra money.

I feel that the kit manufacturers can easily make , at the same price, with
very little effort more, VCO kits with much better specs than now.

Maybe the reason why they are not bettering their VCO kits is the profit angle.

With that, my case rests, and thanks for a lively discussion !!!

2949. List Of Stamp Applications [980926]

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-27 00:00:00 UTC
From: cjX@hth.com
Message-ID: <360e9093.243540399@news.buller.se>
Source record: 78668
Cross-posted to: comp.robotics.misc,comp.home.automation,sci.electronics.misc,rec.radio.amateur.homebrew

Below is the latest index of L.O.S.A and you can download the
complete L.O.S.A from the following places...

WWW:

http://www.hth.com/losa.htm

FTP:

ftp://ftp.parallaxinc.com/pub/text/losa.txt

1.0 What is L.O.S.A all about?

This list was started back in -95 when I heard about (more or less)
uniqe problems that was solved by using a BASIC Stamp. Especially
Guy Gustavson's story (see #001) about how he saved his beloved cat
Kesha gave me the inspiration to start writing L.O.S.A. I hope Kesha
still is alive and having a great life. Now 3 years later there are
130+ applications described and I hope you will enjoy reading all
(or parts) of them.

The main purpose of this list is to get an idea of what other people
are using their BASIC Stamps for and maybe get some inspiration or
hints for your own projects. Some of the projects described in the
list also have links to source code and schematics for download.

1.1 How can I contribute to this list ?

If you have done something (big or small) with the BASIC Stamp that
you are willing to tell others please use the form given below and
write a short description, nothing fancy is needed just a simple
explanation. If you have source code to share that's even better but
it's not necessary.

Visit the following Web site and fill in the contribution form...

http://www.hth.com/losa.htm

we have designed and used vfo's for years and with stabilitys down to 25
khz drift with average parts. down to 10 khz with a little bit of
chopping and changing the orange and black philips caps. (different temp
coefs.)
its amazing how much difference a 6 turn to a five turn can make to
stability with a slightly different cap across it.

>If they have a VCO kit that currently drifts 100 Khz, while PLLs drift 200-500

true

>Maybe the reason why they are not bettering their VCO kits is the profit
>angle.

The reason many manufacturers may not sell vfo kits is down to the fact
that no legal station can use vfo PERIOD. so how can you say your
products can be used legally. in a court of law you could argue your
pll's can and probably are being used for legal radio stations, it would
be a little harder to argue the same for VFO units.

the above is certainly one of the reasons we have taken the pll line.

>between the isolation required to reduce the frequency pull to a
>certain frequency (say 1MHz)

A VSWR of 2:1 corresponds to about a 10 dB return loss.

If you add a 5 dB attenuator, the return loss will be increased by
10 dB (it doubles because of the round trip thru the attenuator).
Now the effective return loss is 20 dB. The VSWR corresponding
to a 20 dB return loss is about 1.2:1. The load resistances
corresponding to VSWR=2:1 and 1.2:1 are 100 and 60 ohms respectively.
The former case corresponds to adding 50 extra ohms and the
latter 10 extra ohms. Hence you have reduced pulling by a factor
of 5.

If an amplifier is added, you have to use twice the quantity
forward gain minus reverse isolation as the increase in return
loss.

Yes. About 70% approval last time I noticed. About the same as Nixon's just before his impeachment hearings began. Odd isn't it? Yanks don't care about politics much, but they have an obesession for watching TV. They watch even when they don't like
whats on. When there is nothing else to watch they they will be screaming for his head if for no other reason, than to get his face off their TV. Sometime next Summer probably. Although I consider Clinton to be a BOATANCHOR around the neck of the public this will be my last post on the subject on this NG.

Sounds like Leroy's a bit miffed -- maybe he can't find an IC for one of
his late-model radios. I bought a couple of Larry's S-meters and
they're exactly as described, and it's hard to buy a new meter of any
kind for that price.

Oh, and anybody who's ever soldered knows it's *not* something one does
naked!

I'm no RF engineer, but it seems like the spurs from the PLL could be easily filtered. Is this not the case? How do they make all of the radio gear that uses PLL technology meet the type acceptance standards?

I know what you're saying, but a VCO is just a poor way of making a stable RF frequency reference. I think the quality of the parts required, and the fact that you'll probably have to put the entire oscillator in a temperature controlled "oven" will make it ultimately more expensive than the PLL. I'd prefer an LC circuit if I was going to build a cheap RF oscillator. Look in the ham radio literature. Ham books are a great source of information such as what you want. I don't think you'll find any VCOs being used except inside a feedback loop (a PLL). I'd investigate the LC oscillator angle for a potential cheap RF oscillator source that's simple to understand. Maybe you can find a kit for such a device out there.

I would think that you'd end up spending the same or more money to create an adequately stable VCO as you'd spend on the PLL system. I think that's the main point. If you have a tested, proven technology to create a stable frequency, and it's cheaper to build, then why work so hard to make a different technology do the job? The kit builders probably realize that.

I'm not saying that it absolutely can't be done, I just bet that a good VCO will cost as much as a better PLL.

If you have a good design for a VCO kit that will do a good job and be competitive, there's your niche. You should be selling these kits. If you can make good money, then there's the proof that you're right about the market for such a device.

Good luck with your project in any case. Maybe someone who knows more about all of this than I do will suggest either a good VCO circuit for you, or can point you toward a supplier of such a device.

In any case, have fun with the whole thing. Learning about all of this is a good part of the fun.

Jim H.

>

The inductance value needed is set by the MINIMUM current that the radio takes, with a choke-input power supply the design criterion is to not let the rectifiers all simultaneously turn off. Reducing the inductance will eventually spoil this, so that rectification ceases to give the mean value as the DC output, and tends to give the peak value. Choke filters give a dramatic rise in DC voltage when off-load, and the choke inductance/mains frequency is what sets the load current below which the voltage rises. Removing the audio output valve from some old radios used to let the reservoir capacitor's potential climb to enough to destroy an old component. It was common to rely on the class-A bias quiescent to keep the power supply under choke control.

Cheers
David GM4ZNX

****

An EXCELLENT experiment to illustrate that a composite
modulation envelope can go to zero while the individual
components don't change !!! Good thinking. I wish I'd
suggested that.....

I've used these for switching thermostatically controlled heating loads, cycling on/off every 30 sec or so. Worked really well, and it was a 7 Kw load! Had a couple of failures - the thing would fail in "latch on" mode, disaster prevented by supervisory circuitry. I've also found that some types have significant leakage when off, lost an HP printer power supply that way. I suspect that the output switch section (triac or anteparallel SCR's) was acting as a rectifier with high forward V.

Overall a good gadget, but some mechanical switching controlled by suitable supervisory circuitry is good insurance. And don't forget to provide an adequate heatsink when controlling high currents.

baggybobs' buck a bag bargain bonanza
brought to you by bob & kim

Surface mount parts for experimenters/prototypers
all new surplus unless otherwise noted

Shipping to the USA
Small parts orders (less than $35 usd). I ship by priority mail. Cost is $3

Larger parts orders I will ship by UPS. Cost is $5. I ship UPS COD only
upon receipt of $10 deposit. I cannot afford the cost or hassle of
refused COD shipments.

Really small parts orders (up to $5 surface mount parts only !!!). Send
me a dollar. I will ship first class mail and put in some foam filler to
prevent damage.
International orders require international money order or funds drawn upon
a US bank. We can determine together the best way to ship.
.
If you have tech questions please e-mail. I will answer in a day or two.

>band.....

Depends on how old they are as to how you can use them. The very
old units, such as the KARS-8 that I have, use a 1 watt klystron as
the signal source. This is easily tuned down from 10.55 GHz into
the amateur band. Most will tune down to 10.3 GHz without modification.
There's a mechanical tuning screw on the klystron for gross frequency
adjustment. Fine frequency control is done by varying the repellor voltage.

That's also how you can FM modulate it. Put a winding of an audio
transformer in series with the repellor voltage and feed audio to the
other winding, just like you'd do to plate modulate a Class C stage.
Instead of AM, what you'll get is WBFM.

The klystron acts as the local oscillator on receive. It does this
via a small metal tab in the radome of the antenna which reflects
some of the transmit signal into the receive horn. (Transmit and
receive antennas are a pair of horns mounted side by side in the
enclosure.) The receive horn has a mixer diode, a IN21B, in it.
The LO and the distant signal mix in this diode to produce the
IF signal.

In normal use, the radar acts as a zero IF receiver, also called
a DC receiver. The diode is followed by a sensitive audio amplifier
which ultimately feeds a limiter and a frequency meter calibrated
in MPH. It also drives a speaker which lets you hear the doppler
of the radar's target.

Now a DC receiver isn't suitable for receiving WBFM, so you
have to tap the diode output and bring it out to a FM receiver.
A FM broadcast receiver works well for this. If you tune a
pair of units so that they are offset by 88 to 108 MHz, you
can tune them in directly on the FM broadcast receivers.

The receiver AFC can compensate for drift between the
two units, but the AFC probably won't have enough range
to do this directly at IF. What you'll want to do is to tap the
receiver AFC and use it to vary the repellor voltage to

keep the units locked together. This works well, but only one of the two units can have AFC turned on. That makes it the slave of the other unit. If you try to run AFC on both, they'll oscillate.

Now if you have a newer unit, it will use a Gunn source. This will be much lower power, somewhere in the range of 10 mW to 100 mW (likely toward the low end of that range). There will be a tuning screw in the cavity in which the Gunn diode is mounted for gross frequency adjustment. To modulate a Gunn source, you have to vary the diode current. You can do that with a series pass transistor.

Receive is again a zero IF system, with a detector diode mounted in the same cavity as the Gunn diode, but isolated from it by a divider. You can again take the output of this mixer diode and feed a FM broadcast receiver with it.

Some of the newer units are a bit more sophisticated. They have a microwave preamp transistor and a conventional superhet receive section instead of the simple diode mixer. This improves sensitivity a lot. These require a bit more thought to modify into a ham transceiver. Details will vary according to the design of the particular unit. I haven't tried to modify one of these for amateur use yet, so I can't give any specifics.

Now if you want to use a narrowband mode, such as SSB or CW, you have to stablize the sources very well indeed. The simplest way is probably to injection lock them to multiplied crystal references. Both the klystron and the Gunn source will tend to lock to the frequency of a signal injected into their cavities (this works for magnetrons too).

The other way is to make a conventional PLL and lock the source to it either by controlling repellor voltage or diode current, for the klystron or Gunn diode respectively. This is problematic due to the need for a divider that will work at 10 GHz. You may want to do a hybrid design by using a multiplied crystal source to hetrodyne the output of the 10 GHz source down to a frequency range where easily available dividers will work.

Once you have the source stablized, you can build a transverter for use with an amateur multimode rig as the IF. I haven't done this, but there are articles in the amateur press detailing how to do it.

Starting out with WBFM is a very easy way to get started on 10 GHz. Operating narrowband modes requires quite a bit more work to get the sources stablized, but of course can give you more range.

> Use a double gate MOSFET and apply agc to the second gate.

Using a dual gate mosfet is about the worst thing one could choose
for a low sideband noise oscillator because of its excessive
1/f noise that is modulated onto the carrier.

In Rohde's (new) book "microwave & wireless synthesizers"
isbn 0-471-520 19 -5 is a chapter on oscillator amplitude
stabilization. He avoids the diode and sets the fet bias
precisely instead (probably not so good for mass production).

In the crystal osc section is an oscillator with a
bipolar transistor that has AGC by adding rectified RF
to the emitter voltage, but he writes:

"saturation should be avoided at all costs in oscs designed
for low phase noise....Although very good performance can be
achieved by lightly cutting off the transistor, the best performance
is obtained with voltage clamping and AGC. A well-designed osc
using cutoff will give much better performance than a poorly
designed circuit with AGC, however.
In general, the signals in the oscillator should be fairly
sinusoidal since linear operation reduces the mixing of low
frequency noise with the osc signal."

"Voltage clamping" in the text above does not mean the
gate diode but using a Schottky diode to slightly clip
the peaks against a dc voltage of several volts.

Hello, I have the following literature that is out of print,
and very hard to find. These are very high resolution LASER
monochromatic reprints of the rare originals. All are professionally
done with original style binding. All sales final on literature,
and I'm sure you'll be pleased. All prices INCLUDE POSTAGE, in the
continental USA. Others by actual quote.
Thanks, and if you need tubes, visit our sister screename,
Tubecntral@aol.com

TRANSFORMER BULLETINS/CATALOGS/MANUALS:

KENYON "Quality transformers",23 pages,has some writing in numbers
on the front cover by the original owner,but a real information
getter. Covers ALL transformers available in Dec.1st,1941.
Even has the "blown in" price update sheet! Price $9.00.

PEERLESS Transformers, Catalog 1948 - 1,original owners name
on upper right hand corner, nice info, not perfect but nice,
Price $8.00.

SNC Transformers, January 1, 1947,13 pages plus original owners name
spelt on upper right hand corner,beautiful copy, has "blown in"supplimentary
catalog page,price sheet, and August price update sheet! Price $8.00

STANCOR Essex #2,069,42 pages, a REAL NICE MANUAL/CATALOG,has EVERY thing!
A real good info source,Price $10.00

STANCOR Essex Catalog # 140 H, 21 pages plus Numerical index and
October 1, 1948 price update list, very nice, $9.00

THORDARSON "Transformers by Thordarson, No. 400-FX 1942, A beautiful
source of info, 27 pages, Price $9.00

THORDARSON 1941"Tru-Fidelity by Thordarson, an UNBELIEVABLE catalog, real
nice pictures of early Broadcast transmitters and an excellent source
of audio info, 19 pages,real nice. Price $10.00

UTC Transformers, reactors, filters, Catalog# 500,looks like early 40's
another real nice, illustrated Catalog/manual, 22 pages, Price $9.00

UTC transformer components, Spiral-bound Excellent catalog/manual,
really in depth, Bulletin# PS-405,)ct. 15, 1941, includes "blown in"
price update for Dec. 6, 1946.Another excellently illustrated info
source, 34 pages, Price 11.00

EITEL-McCullough's "THE CARE AND FEEDING OF POWER TETRODES", 1951
25 pages crammed full of information IN DEPTH! Has everything you
ever wanted or needed to know about running these tubes, a real

nicely illustrated easy to understand manual, Price 10.00
Thanks for reading, if you have any questions or need to order,
Please respond to my mailbox...

: > Diameter in millimeters = 10^(-0.05035 * AWG_number + 0.9164)
: > For guages larger than 0, use negative values, ie 000, use -2

: A somewhat related and easy-to-remember rule of thumb: for every
: increase in 3 wire gage sizes (i.e. #30 to #27), double the CMA
: (circular mil area), weight (per unit length), and current capability.
: Resistance (per unit length) will be halved.

: If one can remember that #30 AWG has a CMA (circular mil area) of
: approximately 100 (actually it's 101) and #10 AWG measures about 1 ohm
: per 1000 feet and can handle 15A, one could construct a wire table from
: scratch!

It was pointed out to me recently that this makes the AWG scale very
similar to a decibel scale: that is, if you think of the AWG number
as dB, and the diameter as "volts", you can use the db <--> volts
math you already (may) know to get from one gauge to another.
20 gauge-numbers gets you a 10:1 variation in diameter. Then resistance
and cross-sectional area are like "watts" on the dB scale. A bunch
of second-nature rules-of-thumb that I use all the time with dB
suddenly become available to work with wire gauges.

I have a 440 RF Amp that needs work.

Depending upon the Antenna and Tuner,
the AMP won't turn off when RF drive is removed.
Using a 50ohm load, AMP appears to work OK, does turn off.

1 Watt in produces nearly 25 watts out from 13.8 volt input.
Is a NO_NAME swap meet special.
Suspect amplifiers stability with 3 series stages.

Need data sheets for Power transistors and source for replacement parts.
Need suggestions how to stabilize, make independent of RF LOAD.
Schematic is available as scanned graphic file.

Uses 3 Power transistors stages in series, marked as follows:
First stage - SSM 1135E 89T

2nd Stage - SSM SP1135 B122

3rd is Output stage - SSM SD1088 B21T

So far, web search for SSM company -Nothing Found.
Are 2SD1088 and 2SD1135, correct transistors?
Who is SSM company, and who makes replacements?

Thanks for any hints.

73, W6MIK

Those who still aren't grokking should cogitate on the fact that a 100
MHz unmodulated carrier crosses zero 200 million times per second.

Anyone interested in the Quadradyne demodulator can look for an article
published in RF Design Magazine March 1993 page 92 entitled: Educational
Project for Electronic Engineering Students by Yvon Roy.
.The quadradyne demodulator (I named it this way) because it
can correct for quadrature distortion of SSB with carrier. It is a
method of transferring the envelope of a received signal to a locally
generated signal using FM modulation. To make it simple, imagine a
receiver with an IF of 500 Khz; the IF signal is fed to a 10,7 Mhz
FM modulator, the modulator is generating FM sideband frequencies
at every 500 Khz on each side of the 10.7 Mhz carrier. The envelope
of the IF signal which carries information (voice) varies in amplitude
thereby changing the modulation index of the 10.7 Mhz FM modulator.
If we look at the signal with a spectrum analyzer, we will see that
when the 500 Khz signal envelope is at its peak, the FM modulated
carrier disappear (Bessel function) when the the envelope is at its
minimum, the FM carrier is at its maximum. If we pass this carrier
of the FM modulator in a 10.7 Mhz bandpass filter which eleminates the
500 Khz sidebands, we have an amplitude modulated carrier. The 500 Khz
IF signal information has been transferred to the carrier of the 10.7
Mhz FM modulator. At first, someone could say that this is equivalent
to demodulate the 500 Khz IF signal followed by an AM modulator at 10.7
Mhz. It is not as simple as that. I will continue if there is interest
in this new discovery. Regards! Yvon VE2AUC

True about swinging chokes, but the question was: "Does anyone know
where it is possible to obtain smoothing chokes for valve HT PSUs? "

Swinging chokes are very rare, have seen just a few applied in
receivers, they are more common in transmitters, the bleeder resistor is
also important......

Hi

I have been asked by a visually impared ham for help hooking up
his Talking Digital Dial. Trouble is, I know nothing about it, and
info for it is very limited. Is there anybody out there that can give
us some advice ? It's a TDD-2B, and he wants to connect it to
a Heathkit HW-12 (?) single band transceiver.

I am wondering about power levels that the thing can tolerate
as well as where the heck would one pick off the necessary
frequency and power level to make the thing work. I understand
that it was hooked up and working on an FT-77, but it had a
plug on the back to accomodate this unit.

Any help would sure be appreciated.

Regards
Reed

73 had plenty of articles in the late 70's/early 90's about converting various CB sets to 10M, and a number of them were about the HYGAIN board (which I understand was used in a variety of CB sets). Among them was one article (plus a followup or two) about using it on CW, and another on using it for FM. Unfortunately, I can't provide exact dates.

QST had an article, I'd say in 1981, by Bob Heil about converting a HYGAIN set to 10 meter FM. It even had a schematic for the CB set (albeit in compact form). The ARRL has various bibliographies online, and I believe one of them is about converting CB sets. It would be in a technical area on their website at http://www.arrl.org From the latest issue of QST, I see that they now have an online index of QST's, though apparently in a section for ARRL members only.

Converting a CB set to FM, once the conversion to the appropriate section of the 10M band has been accomplished, would consist of FM'ing the transmitter (I can't remember, but I assume the articles disable the AM modulation of the final amplifier, and feed some of the audio to the VCO), and adding an FM detector to the receiver. The two articles I can remember used IC detectors, which would add some IF amplification and limiting before the detector. One thing worth considering is that you can easily scrounge up a 455KHz FM IF strip from a cordless phone, or a 49MHz superhet walkie talkie.

For Sale: Ameritron AL-1500
Brand New. Never Used. As shipped from factory: Transformer and the Triode tube are included but not installed. Purchased for $2,600. Best offer will take it. Must sell, any offer within reason will be considered.

Specifications:

Full Power Linear Amplifier. The Ameritron AL-1500 is a 1500 Watt output linear amlifier that oprates from 160 through 15 meters. It uses a single 3CX1500A7/8877 tube in a class AB2 grounded grid circuit. CW, FM and TTY efficiency is improved by shifting the bias deeper into class B. He heavy duty power supply and RF components, combined with a forced air system utilizing a chimney, proved long service love for expensive components. The AL-1500 is shipped factory wired for 240 volt, 50/60 Hz Power mains.

Its the distance between anode and grid around any convenient wiring which sets the parasite frequency. A half wavelength is a good starting point for estimating frequency. There is a 180 phase shift between anode and grid. Other modes will oscillate just as easily. And it only needs a gain of 1.0001 to set it going.

A half wave at 300 MHz is 500 mm. Thats a long way.

> not. How do you explain this apparent paradox?

Look at it this way: You have one carrier and two sidebands; so you
have 3 different frequencies; the vector addition and substraction of
those 3 frequencies
will make it to cancell at some point (Zero envelope, not zero carrier)
at some other point, they will all add up to give the peak of the
envelope. Carrier and envelope should not be misunderstood. In AM
the carrier is fixed in amplitude, but the presence of the 2 sidebands
makes the envelope to vary from zero (when 100% modulated) to the peak,
A simple experiment to understand what is meant by envelope can be made
with 2 signal generators. Connect one generator at a frequency of 1 Mhz
to input one of a scope; connect another generator at a frequency of
1.1 Mhz to input two of the scope; both generators should have the same
level and both input of the scope should have the same gain. Now switch
to input one or two, you will have a continuous wave (CW) Now operate
the scope in the "ADD" mode, you will see the envelope vary from zero to
twice the level of generator one or two outputs. Note that the envelope
is not sinusoidal, it is distorted; this is called quadrature
distortion.(An inherent distortion of SSB) In order to be sinusoidal,
another sideband at half the amplitude is needed which is called AM.

No Reg, it's just an opinion. Mine is that the most effective is
modeled on the original Vomax circuitry that N7WS copied in his
processor. But it can be made more effective by modifiying the
response to sharpen up the filters and shift their center frequencies
to eliminate (in large part) the 600-1200 Hz band. That removes most
of the vowel energy and results in more power into the consonants
which is where the intelligibility lies. This can be followed by a
small amount of RF clipping which is quite effective. In fact, for
95% of amateur use, a tailored response microphone (like the D-104)
and some RF signal processing is by far the most effective. But it's
not necessarily the easiest.

The use of clipped waveforms is not very effective on SSB, Reg. If
you look at the analysis in Sabin and Shoeneke's epistle, you'll see
that a square wave input results in an output waveform that has an
infinite peak to average ratio. In fact, what you should be aiming
for in processing is a diminished peak to average ratio.

While I never published a paper on the results of incorporating Don
Stoner's work on vocal formants with the performance of the sub-octave
filter/clipper/filter approach, a search of the periodicals should
make it clear that N7WS's approach (which he did not attribute to
Maximillian Associates in his article) combined with the work done by
Stoner, is clearly the most effective communications tool for SSB
audio processing yet developed.

Another approach, taken in the KWM-380 and described by Sabin, et al,
is to generate, at audio frequencies, an equivalent waveform to that
resulting from RF processing (clipping/filtering). This approach,
while elegant, simply refused to provide the desired increase in
intelligibility unless substantial pre-shaping of the audio response
contour preceeded the processor.

So, Reg, going back to the old B&W approach to audio processing ain't
gonna buy you much except distortion and noise--things we would all be
better without. And even though I am critical of N7WS, himself, for
not citing preceeding work, his approach to a practical implementation
of the multi-band processor was very satisfactory and very effective
in actual performance.

From: Harry Lythall <no.one@no.where>
Message-ID: <6ur66jmik1@zingo.tninet.se>
Source record: 78539

Hi all,

I am looking for a USA supplier that supply almost anything, such as of RF transistors, PCB prototyping, components, batteries, bulbs, soldering irons, kits, power sockets, you name it. If I were in the UK I would go to Maplins, CirKit and (if I were rich) RadioSpares. I have never lived in the USA so I am a bit ignorant of US suppliers.

I have already found Antique Electronic Supply Co and Debco who each have their own special properties (especially AES - great for tubes) - but what about the rest?

What I am really seeking (at this moment) is a source of UV tubes for a PCB exposure-box, but they cost $20 a piece from the UK and I have found that the US is usually a lot cheaper. I live in Sweden where they cost more like $45 each (+25% sales tax!).

Anyone got any ideas? Please reply to:
sm0vpo@hem2.passagen.se

616BNG1063

Inside on a label on the PC board is

Korea 8820 NRD6855AN 1 TD289

And printed on the PC Board is the number 6855

I came across this pager quite cheap and thought it would be fun to try and convert it to 2 meters for local use in ower small town. Any information you could provide would be appraised

Thanks again Doug VA3DMB

Dave asked for something simple. I suggested something which is not only simple but, from much experience, is also highly effective.

I'm sure there are very effective micro-processor based, very expensive, black boxes around these days which are 2 dB, or 1/3th of an S-point better but still sound like Donald Duck.

Adding some more perhaps useful trivia to what I wrote yesterday:

: Joe Dubner (dubner@comtch.iea.com) wrote:
: : Wes Stewart N7WS <n7ws@azstarnet.com> wrote:

: : > If the reference you are looking at is in the US, then the numbers
: : > refer to AWG (American Wire Gage).

: : > A fairly accurate conversion follows:

: : > Diameter in inches = 10^(-0.05035 * AWG_number - 0.4884)
: : > Diameter in millimeters = 10^(-0.05035 * AWG_number + 0.9164)
: : > For guages larger than 0, use negative values, ie 000, use -2

: : A somewhat related and easy-to-remember rule of thumb: for every
: : increase in 3 wire gage sizes (i.e. #30 to #27), double the CMA
: : (circular mil area), weight (per unit length), and current capability.
: : Resistance (per unit length) will be halved.

: : If one can remember that #30 AWG has a CMA (circular mil area) of
: : approximately 100 (actually it's 101) and #10 AWG measures about 1 ohm
: : per 1000 feet and can handle 15A, one could construct a wire table from
: : scratch!

First, thanks to Reg for the history lesson! It's also interesting that
AWG is known as B&S gauge (Birmingham and Stubbs??)

For a reference point, it's probably useful to remember 36 gauge as
exactly 5 mils diameter. I understand that AWG is defined as
exponential thru that point and 0000 gauge = 460 mils diameter.
That means that, by definition,

d(mils) = 5 * 92^((36-G)/39)

Another useful approximation I have noted (but that was before I
started thinking in terms of dB!) is that for copper wire near
room temperature,

R(1000 feet) approx.= 10^(0.1*gauge - 1)

which remarkably has only integer powers of 10 in the constants!

Of course, I've noted all of these little factoids in the wire
table I always use, and not committed them to memory, so I end up
using the table rather than the formulas anyway. ;-) But...the
formulas are a good way to put the wire table in my programmable
calculator.

> What does a "carrier" carry?

I'm going to presume that your questions, asked from hp.com, are intended to make one think rather than to get basic information. :-) So remember, I'm the one who brought up the definition of 'modulation'.

If I had to define the first, in light of today's modes, I'd have to say something like "that reference frequency which is modified by information signals to transmit the information by electronic means".

Since the carrier doesn't necessarily accompany the information, I'd have to say that when it does, it carries signaling information that is usually used to facilitate the demodulation of the transmitted signal.

What was the point you were making? I was originally expressing that the fact that the carrier sits unchanged on a spectrum analyzer display is a red herring, and used the zero-crossing thing as an analogy.

Search the web for padsdemo. It's the demo free version of PADS PCB.
Does schematic capture, layout, autoroute, has extensive component library.
Can't beat it for the price.

If you try to use a cad drawing program, you can do it if it's right the first
time.
Typical CAD programs aren't very freiendly when you have to move an IC.

my k-band gunn unit was a surplus police speed unit. no varactor. it is built from a solid block of copper (heat sinking). i modulate the gunn voltage with low level audio. for wide-band operation, this is fine. this likely wont work for narrow band, as the modulation voltage will reduce to microvolts, for 15khz bandwidth. the gunn noise will wipe this out.

From: Alfred Lorona <w6wqc@juno.com>
Message-ID: <36119FB3.2C48@juno.com>
Source record: 78553

Not wishing to beat an old dog to death, or however the saying goes, this should be my last posting. Honest.

My original question was not to solicit definitions of modulation as it was to ask how we can reconcile the two conflicting explanations of amplitude modulation found in every text book. This is that the carrier varies when we look at it in time but does not vary when we look at it in the frequency domain.

Now a tube is dumb. It neither knows nor cares one whit about us humans, our thinking, our instruments and our mathematics. It sits there being modulated. And the carrier is either varying or it is not INDEPENDENTLY OF WHICH WAY WE LOOK AT IT. You would think that moving electrons, being a physical phenomena, would yield to clarity of explanation. But this appears not to be the case.

And no one has yet addressed by second posting and explained how a steady un-varying carrier can be produced by a tube whose plate voltage is varying from twice the DC value down to 0 volts.

At this stage perhaps it is appropriate to put the questions in the following form: Is it possible to say that the carrier is varying or not varying - yes or no.

If the answer is yes, then what is it, yes or no.

If the answer is no. Then why not?

Interesting philosophical questions, folks. It's been fun. 73, AL

>if it *doesn't* get warm, it's probably very good indeed at HF).
>
>Roy Lewallen, W7EL

I tried to build a 'compact quad' once, using PVC insulated wire. This
was a design that was diamond shape with a wire from each side corner going
across the middle, forming a two-wire capacitor.

The RF field on this capacitor was high enough that it melted the PVC
insulation. The wires themselves did not get hot. The melting was only
in the area of the capacitor.

I agree, however, the dielectric properties of such things are not
constant with frequency. Complex molecules, such as PVC, have resonances
where they will soak up all the signal.

What about fiberglass? Or polybutal?

3017. UHF 280W Power amplifier on +14VDC?

Newsgroup: rec.radio.amateur.homebrew

Source record: 78618

Hi
Bought a 70cm 280W surplus PA from OE2WIM. TTE1622A, circulator (1,3dB)
at the output TTE1482A. No manufacturer mentioned, it might have been
made in Asia. Believe it has been used in Austria.
RF power devices are marked: Pre-Driver: M1107 185 8745
Driver and PA (2*): 185 11L60 8831

wonder what the power devices could be compared to, believe M1107 and
11L60 indicates sort of manufacturer's code for the devices.

any suggestions?

Where can I find a description of an HF amplifier (160 up to 10 meters) using only one tetrode (4CX350A).
I'm working at a NMR research lab. Our spectrometer uses 4 of those 4CX350A tetrodes in two different amplifiers (push-pull amplifiers). My idea is to built an HF amplifier in order to pair the new tetrodes up. Of course, this amplifier could also be used in my hamradio shack!

I thank you in advance.

Only the tuned circuits are different from any other 4CX250/350/400 amplifier

so the PSU is identical. For RF, look at the ARRL design using the 4CX1000.
Modify for the correct base. The anode capacitance is different but this is
of
little consequence on HF with a PI-L output circuit. The grid capacitance is
also
different and might need a little messing about with the input capacitor
value to
compensate.

You can expect 400W linear output with a good screen supply (G3SEK does
them).
Better to use 2 in parallel.

I was looking at an old issue of "73", Oct 92. John AA4AW
describes a 2m FET amp using a Motorolla MRF137. Since the
article is somewhat old, I was thinking that there might be
better replacements around. Does anybody know? This is
such a simple circuit, too; I'd hate to complicate it too
much with something terribly different.

Thanks,

3028. SSM RF Transistors

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-29 00:00:00 UTC
From: af389@lafn.ORG
Message-ID: <3610DB6C.3282C5A3@lafn.org>
Source record: 78629

I have a 440 RF Amp that needs work.

Depending upon the Antenna and Tuner,
the AMP won't turn off when RF drive is removed.
Using a 50ohm load, AMP appears to work OK, does turn off.

1 Watt in produces nearly 25 watts out from 13.8 volt input.
Is a NO_NAME swap meet special.
Suspect amplifiers stability with 3 series stages.

Need data sheets for Power transistors and source for replacement parts.
Need suggestions how to stabilize, make independent of RF LOAD.
Schematic is available as scanned graphic file.

Uses 3 Power transistors stages in series, marked as follows:
First stage - SSM 1135E 89T - no threaded stud

2nd Stage - SSM SP1135 3 B122 -has a threaded stud

3rd is Output stage - SSM SD1088 B21T

So far, web search for SSM company -Nothing Found.
Are 2SD1088 and 2SD1135, correct transistors?
Who is SSM company, and who makes replacements?

Thanks for any hints.

>> via e-mail
>

Here's some commonly used materials:

G-10/FR-4 fiberglass-epoxy: ranges from 4.5 to 4.8 by my measurements
Alumina: 10
Teflon-fiberglass board: 2.5
Rogers Duroid 5870: 2.33
Rogers Duroid 5880: 2.2

I picked up some goodly-sized pieces of 0.016 inch double-sided board at a hamfest for a dollar a couple weeks ago that looks like Duroid. I haven't measured the dielectric constant yet, but it looks like I got a deal! Anything that is VERY soft and flexible is probably teflon or Duroid.

Source record: 78631

Tom, what a very interesting way of describing the wire gauge system.

The wire gauge system was invented in Birmingham, England, I think, around 1830. In those days Birmingham and the area just to the west was becoming the world's centre of precision mechanical engineering, sometimes described facetiously as "metal bashing". Electrical engineering had not been thought of. Boulton and Watt's factory in Soho had to work to very close limits in the manufacture of smooth-running steam engines to drive lift cages and pumps in the coal mines, spinning gennies in the cotton mills and machine tools in the new manufactories. Wire drawing requires precision engineered machinery. The measuring gauges used by "quality control" inspectors needed even greater precision to manufacture.

Iron, steel, brass, copper wires were begining to be used in great quantities in many different kinds of manufactured products. Silver wire was (and still is) used in the manufacture of jewellery. "Made in Birmingham" appeared on the packaging of manufactured goods world-wide, from pins, buttons, medals and coins, to kettles, steam hammers and other giant machines used in industry.

The most expensive part in a wire drawing machine is the "die" which contains the hole through which the wire is drawn. The finer wires are obtained by drawing through successively smaller dies. But the amount of reduction at each successive stage is limited. So adjacent wire diameters all have the same relationship to each other. Even from the wire-user's point of view it was economically sensible to restrict the number of diameters available for sale. As engineers in those days were just as familiar with log tables and exponentials as we are, and wire sizes increase/decrease exponentially in a natural manner due to manufacturing economics, what better method of standardisation is there than one based on logs to the base 10. As you say Tom - just like decibels.

The North Americans of course, in Cincinatti, Pittsburg and Detroit, when they eventually got around to drawing their own wire, some of it for electrical purposes, and Birmingham, Alabama was not (then) an engineering city, could not possibly use a system "not invented here" and felt obliged to change the constants in the mathematical formula. Also the name.

So BWG became AWG.

A more convenient formula is -

Diameter = 0.3248 * 10^ (- AWG / 20) inches, or

Diameter = 8.25 * 10^ (- AWG / 20) millimetres.

Don't forget the minus sign.

If you don't object to fractional AWG numbers, and by going the other way
around -

AWG = 20 * Log (0.3284 / inches), or

AWG = 20 * Log (8.25 / mm).

Worked any good DX lately ?

From: af389@lafn.ORG
Message-ID: <3610EAB1.70AF1163@lafn.org>
Source record: 78632

Hi,

Can anyone suggest an approach to servicing a
home brew 440 Linear Amp with following trouble?

When keyed on from 440 HT, AMP
won't turn off when HT is turned off?

Won't turn off happens when load is 440 beam ant.
Beam vswr is about 1.5:1
Amp turns off OK when load is 50 ohm dummy load.

1 watt in - 25 watt out from 13.8v

Unit is homebrew..swap meet special....bought years ago
and now trying to use it....not so good.

Thanks for any thoughts.

Source record: 78634

The most simple and very effective speech processor circuit for SSB use consists a 10K series resistor followed by a pair of back-to-back silicon signal diodes down to ground.

This clips the output speech waveform to about 1.2 volts peak-to-peak.

The high frequency audio distortion products will be removed by the following IF sideband filter.

An audio gain control before the clipper will set the amount of clipping.

An audio or IF gain control following the clipper will set the transmitter PEP (Peak Envelope Power).

I've never felt the need to use anything else.

For really sharp clipping, instead of a pair of silicon diodes, use a pair of low power, high gain, small-signal transistors such as BC109's. Connect each collector to its base. Then connect the transistors back-to-back as with the diodes.

A perceived 6 dB or 1 S-point improvement in received signal-to-noise ratio can be obtained before audio distortion becomes noticeable. Beneficial up to 9 or 12 dB of clipping in the presence of severe noise.

Hi,

I'm thinking of reducing the harmonic content of a homebrew VCO (500 MHz - 1 GHz, Pout -5dBm) by using a varicap tuned lowpass filter connected to the VCO's output.
Is this a good idea or will the the varicaps even create more harmonics?

Peter

I have assortments of teflon insulated hookup wire for sale.
ten - 50foot rolls (500' total) of stranded , silver plated ,teflon
insulated hookup wire 22AWG. 10 different colors in each pack.

Will ship prepaid via priority mail in USA for $20 per pack.

The wire is rated to 200 degrees C and solders very easily.

That's 4cents a foot and includes shipping...compare at
$280 plus shipping for 1000' from Newark electronics !

Will also trade for the following which I need for another project:

100Mbps, PCI bus ethernet adapter with RJ-45 connector and autosense

Category 5 round cable

RJ-45 plugs for above cable

RJ-45 crimper for above plugs

Category 5 flushmount wall plates and RJ-45 jacks

> in this new discovery. Regards! Yvon VE2AUC

Continuing:

In order to understand what is meant by quadrature distortion in the
"QUADRADYNE" detector system, I will give a simple example: If we
connect two sinewave 1 Mhz and 1.1Mhz generators having identical

outputs to a power combiner and observe the resultant on a scope, we will see that the envelope contains a quasi-sinusoidal signal which is the difference in frequency (100 Khz) between the two generators. We can call this a single sideband signal with carrier modulated 100%. The envelope is not a perfect sinewave because the resultant vectorial sum of the two frequencies is due to both AM and PM. We say that the system contains quadrature distortion due to ANGLE (phase) modulation. This is a natural phenomena and it exist in every system of single sideband with carrier or vestigial sideband (Unequal sidebands) as in TV transmission. The only way to detect such signals without quadrature distortion is to use synchronous demodulation or the new QUADRADYNE demodulator. Here is how the "QUADRADYNE" detector functions: If we feed a sinewave signal to a FM modulator and observe the phenomena of the first carrier null (Bessel function) by using a spectrum analyzer and then make a measurement of sinewave signal amplitude feeding the FM modulator versus FM carrier amplitude reduction, it will be found that the transfer function is not a straight line, it is not linear; when I found this phenomena in 1992, I realized that the transfer function had a characteristic which is the reverse of quadrature distortion. So if we feed a single sideband signal with carrier, having quadrature distortion to a FM modulator, the AM effect on the FM carrier (Excluding the sidebands) due to the first carrier bessel function null, will yield a AM
double sideband signal with a sinewave envelope which can be detected with conventional methods. Hence the word "QUADRA" for quadrature and "DYNE" for beat. To be continued. Regards! Yvon VE2AUC

3044. Re: SSM RF Transistors

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-30 00:00:00 UTC
From: Michael May <r39031@email.sps.mot.com>
Message-ID: <36124D12.F6E42D51@email.sps.mot.com>
Source record: 78496

3 stages with 1 watt in and 25 out is very poor gain even for bipolars,that equals about 4.7 dB per stage, the devices you mention were made by Solid State Microwaves (SSM) they went out of business around the mid to late 1980's, and they were I believe in Pennsylvania, so finding SSM replacements is probably not possible. If you want to try stabilizing it first disconnect the rf sensed relay and try hard keying the amp by grounding one side of the t/r relay as required, also when drive is removed and the amp stays keyed is it putting out any rf ? this will tell if the amp is truly unstable or if the time constants in the rf sensed relay attack and decay circuitry are all wrong.

As for finding cross references to the SSM devices the SD1088 is equal to an MRF644 still in production 25 watts out UHF 12.5 volt 7 dB typical gain, the sp1135 is close to an 2n5945 which may be hard to find now but is close to a mrf652 stud mount, 5 watts out/1 watt max. in 7 dB typical gain @ 12.5 volts, still made, as for the 1135e I think it is the same or close to a mrf652s which is a non stud mount (i.e. surface mount) version of the mrf652, same specs also still available.

Rf parts company should carry all the devices, the minimum gain for all 3 stages should be 6 dB minimum or 18 dB min total, and 21 dB typical 7db/stage, or about .4 watts in for 25 watts out worst case and typically .2 watts in for full output.

The stages should be as follows: #1 Pin=.2 watts max. in / 1 watt max. out 7 dB typical gain,
#2 Pin 1 watt max. in / 5 watts max.
out 7 dB typical gain,
#3 Pin 5 watts max. in / 25 watts out
for 7 dB typical gain

Also just by the fact that you get 25 watts or so out you may only have a blown 1st stage. For reliability the 652s in stage 1 should not be driven with more than .2 watts and preferably less just to keep the max. drive to the second stage at 1 watt or less, there is a good chance somebody hit it with a 5 watt HT and damaged the first and or second stages.

It sure sounds like someone went to a lot of unnecessary trouble and over designed the amplifier.
You may and probably should eliminate stage 1 and just use a mrf652 stud mount in stage 2 and a mrf644 stud mount in the output with about a 6 dB pad on the input to stage 1 you should still obtain full power out with 2.5 watts of drive from an HT, but if you go this route with 5 watts use more padding at the input to keep the max. drive down to about .5 watts.

I hope this helps; unfortunately I don't think I'll receive your response in time as this is my last week at Motorola RF. Good luck.

HAM stuff for sale:

Ten -Tec Digital Century 21 HF CW Transceiver
80 - 10 Meters, no WARC bands
75 watts input, ~35 watts output CW
Digital frequency display, RIT, switchable audio CW filter
Direct conversion receiver
Built-in AC supply or runs on external 12 vDC

Good condition, slight wear, everything works.
Offset and Tune buttons replaced with R/S buttons.
Slight corrosion near Calibrator jack on rear.
With manual

$175.00 OBO + shipping

Computer stuff for sale:

Rolodex REX PC companion
256K, leather case
TrueSync software
With disks, manual, box, extra batteries
Good condition, slight wear, everything works
$60.00 OBO

Accton EtherPocket-SP Ethernet parallel port adapter
Switchable 10baseT (twisted pair) or 10base2 (coax) Ethernet adapter
With manual, disks, and AC wall cube supply
$40.00 OBO

Microcom Travelporte pocket modem
14.4 K data/fax, MNP-10
runs on battery or AC power
with RS-232 cable and AC wall cube supply
$30.00 OBO

Look at it this way... AM is realy a mixing action:) Ya mix a rf signal with a audio signal. Just like a hetrodyne receiver does. The receiver produces two if's... You just select the one you want. In a am transmitter you produce two if's, one above the carrier and one below the carrier and let em both go:) So, the AM transmitter PA is a MIXER. It mixes the carrier with the audio:) I believe you will find this explanation in several texts. Sure beats fighting over a VAREING carrier:) 50 year Broadcast Engineer 73 all:)

Why not use diodes to switch a couple of off-the-shelf (e.g.,
Mini-Circuits) low-pass filters in?

Better still, retarget your design to use two suboctave-range VCOs
instead of one octave-range one. The reduced capacitance contribution
from the varactor may allow you to improve the overall tank-circuit Q.
Combined with the reduced voltage tuning sensitivity, this will cut down
on phase noise, and you won't have to worry about switching filters or
generating tuning voltage for a tracking filter.

I need a detailed data sheet and/or app notes on either a 6802 (same as CK6802(Raytheon, Sylvania, etc.)), or a GC10/4B(Ericsson). Both of these are cold cathode counter tubes, circa early 50s.

I found a short form data sheet on wps.com, but that's all to date.

Thanks in advance for the help!

I took an interest in this thread because I've had two or
three requests from the US to include inches, feet and AWG
in my antenna and coil winding computer programs.

But, on balance, the risk of introducing program errors, the
amount of programming work involved, and the quality
control checks needed, would not be worth the production
and re-issueing labour. So, over there, you really must try
to get fixed up with the metric system. It's the 'IN' thing.

Had any good DX recently ? I havn't !

3054. ****TRADE: MOTOROLA SPIRIT VOICE PAGERS****

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-30 00:00:00 UTC
From: teenham@aol.com
Message-ID: <19980929223626.13014.00001192@ng09.aol.com>
Source record: 78558

Hey,

I have two Motorola Spirit Voice Pagers (dedicated frequency recievers) for trade. Both include special "custom size" Rechargeable NiCad batteries, one "drop in" charger and one "non-drop-in" charger (the non-drop-in charger can actually charge two batteries at the same time, but you must first remove them from the receiver. The drop in charger is a single reciever charger, but you just drop the pager in and it charges--- no removal of battery.) I'll include both chargers, and of course both belt-clips. Both units work great, and and are in good condition. Both are currently set to 138.325 MHz. I have been told there is a way to change the freq to anywhere from 136-165 MHz (+ or - some) by doing some modification to it, but I just don't have the tools or knowledge for it. Would be usefull for monitoring a 2m repeater, or maybe a fire company freq when all you need to do is listen. WHAT I AM LOOKING FOR IN A TRADE: The 2m amp that RadioShack just cleared out for $29, a glass mount 2m/440 antenna (non-used, of course,) a small base 2m/440 antenna (no home-brew's please,) cheap frequency counter, or just about any other ham radio related item. All offers considered. (In case you're wondering how much these recievers go for, last weekend a person at a hamfest was selling a pair of them for $45 without any charger and one battery.) *ALL OFFERS CONSIDERED* Please drop me an email.

*I'll have to disagree with the ARRL. Yes the carrier
* does vary, in amplitude,
*but at an audio rate, up to 20,000 times a second. So you you are
*not going to see it. On a scope you can, and you can see on negative
*audio peaks where the carrier comes close to being cut off, and on positive
*peaks the carrier twice the unmodulated value. You will noticed on an
*s meter when a well modulated AM signal is running more than 100 percent
*modulation, in the poisitve direction, the S meter will increase, on peaks.
****

The ARRL handbook is correct. In large carrier AM the carrier remains constant in power throughout modulation. Think of modulation as a mixing product. The carrier is multiplied by the audio. Thus the mixing product produces four outputs. The carrier, the carrier plus and minus the audio , and the audio. The audio frequency component is filtered out by theRF cirrcuits leaving just the carrier and the carrier plus and minus the audio frequncy.

On an oscilloscope you see the process of the three frequencies being mixed together in the time domain. The scope shows the varing audio voltages that are adding or substrating to the carrier voltage. Thus the appearnce onthe scope that the carrier power level is changing with modulation. On a spectrum analyzer you can plainly see that the carrier does not change under modulation. The sidebands are the only RF signals that are varying with modulation power due tot he fact that the modulation power of voice is a time varying signal.

Regards
James

****
*An interesting philosophical question, is the carrier infinite small?
*that is does it really occupy bandwith? How narrow can a carrier
*be?? can it be infinite small. hahahha
****

Mathematically Yes. The carrier in the frequency domain is represented by the impulse function. A function of infinitely small bandwidth and near infinite power. In reality such does not exist. Nor does a pure carrier. Small variations in the generation of a carrier always exists. Power supply noise will also cause a modulation of a otherwise pure dead carrier. Thus giving it some bandwidth.

While I agree with your critique of Reg's post, I must add that I did
not "copy" the VOMAX. I have never seen a schematic of a VOMAX, only
a general block diagram. The split-band approach was not new to
Schreuer, VOMAX or Maximillian Associates. Bell Labs did work on the
technique in the 30s I believe, although I do not have the original
references.

Sorry Fred, but I stated in paragraph two that one of my references
was Schuruer, the designer of the VOMAX, and again in paragraph five,

I stated in part "...Fisk had written in glowing terms about a similar unit available commercially from Maximillian Associates."

I believe in giving credit where credit is due. Would you please be so kind.

Please re-read the article. Of the eight references cited, five are for previous work. Furthermore the combining technique I used, which is an improvement (IMHO) over the phase shift networks used by Schureur, was developed by Jim Metzger, W7KTR. He was mentioned in the article and reviewed the original manuscript. He, however, didn't want to take credit for the idea although it was offered.

There were also published follow-up letters by Schureur and the undersigned which made it abundantly clear who did what.

To mix metaphors, you have to be real careful in the criticizing business because sometimes you can open a real can of sour grapes.

Thanks to Danny, K6HME, I now have a PDF copy of my article at
http//www.azstarnet.com/~n7ws

It should be noted that the Plessey SL1626 is no longer available.
Walter Schreuer (sorry, I miss-typed his name in other posts)
correctly pointed out in subsequent correspondence that this wasn't
the best choice anyway. The clipper will be most effective with some
modest compression before it, however, the clipper board can also
stand alone.

As Walter pointed out, minimizing distortion in the preamp/compressor
is *very* important. So, if you build an alternative to the Plessey
circuit, be careful.

I brought up the definition of modulation because it has withstood the test
of time and can therefore be cited to prove that at least the definers
believe the carrier is being modified.

Probably for the same reason no one has noted that you can't see the
sidebands on a time-domain display while you can on a freq-domain display.
We all look at our oscilloscopes and see an tone of changing amplitude and
constant, unvarying frequency; does this prove that the modulated AM
carrier has no sidebands? The oscilloscope display demonstrates adequately
that no other frequency is present other than the (presumably) AF envelope
of the carrier; you definitely cannot see the sideband frequencies there.

If the time domain adequately described everything we need to know, then
the frequency domain would be a useless intellectual curiosity, and vice-
versa.

All either manifestation means is that our models are inadequate to fully
explain the phenomena they describe, like the particle/wave dichotomy.

3059. Re: AM modulation

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-30 00:00:00 UTC
From: Roy Lewallen <w7el@teleport.com>
Message-ID: <3611D5DC.83AD0C9B@teleport.com>
Source record: 78563

An amplitude modulated signal consists of one time-varying voltage or current, not two or three. The "envelope" (peak value for each cycle) of this time waveform varies in amplitude. It's convenient to observe that this one time-varying waveform *could* be made by adding three sine waves of different frequencies. For the simplest case of modulation by a steady tone, these three waveforms are constant in amplitude, but different in frequency. When we add them together, we find that as time goes along, they go in and out of phase with each other in a periodic manner (a "beat", due to their different frequencies), causing the envelope amplitude of their sum -- that is, the AM signal, to vary with time. So the time waveform which varies in amplitude can be created by adding three non-varying sine waves.

One of the three component waveforms is called the carrier. If the modulation is removed, only one component sinusoid remains -- the carrier -- and it's the same as the time waveform.

The component sine waves can be separated with a narrow filter and viewed separately. An instrument which sweeps a narrow filter across a band of frequencies and displays the amplitudes of the components is called a spectrum analyzer. An oscilloscope views the total wave all at once, in the time domain. These instruments present different views of the same signal.

The concept of frequency domain analysis depends on the fact that you can make any periodically-varying (time-domain) signal out of a number of non-varying sine waves of various amplitudes and phases. Conversely, you can, with a filter, split any periodically-varying signal into a number of non-varying sine waves.

3060. Crystal Radio help required

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-30 00:00:00 UTC
From: Richard Podmore <info@monoco.com>
Message-ID: <3611DF3A.2351@monoco.com>
Source record: 78564

My scouts would like to make crystal radios. Not from a kit but from scratch. Can anyone direct me to a site, or send me details, of how to go about such a project?

We are near Rotherham if anyone feels brave enough to want to come along and help.

Could replies be copied to myself as well as newsgroup as I am not likely to be able to look again for a while.

Many thanks,
Richard Podmore

<My original question was not to solicit definitions of modulation as it
was to ask how we can reconcile the two conflicting explanations of
amplitude modulation found in every text book. This is that the carrier
varies when we look at it in time but does not vary when we look at it
in the frequency domain.>

It's a good question, but one that is founded on a misconception. What you
see on an oscilloscope in the time domain is *not* the carrier, but rather the
composite waveform comprising carrier plus upper and lower sidebands.
The carrier component does not vary (and neither do the USB or LSB in the
case of pure tone modulation) but the vector sum of the three components does
vary as the slightly different frequencies change phase relationship
periodically at a rate equal Fc - Fm (the beat note). When they add
constructively, the composite waveform increases in amplitude. When they add
destructively the composite waveform decreases. It is this beat note you see as
the envelope on your oscilloscope.

Cheers,

Blake - ZL3BC

Source record: 78567

This is a great thread and I don't want to cause a deviation from the main theme, but I have a related question.

I've been trying to understand the physics of how the sum and difference products are produced in a mixer. I find it easy to understand how the differnce (beat) frequency results: the old physics books take two sine waves of different frequencies and put one graph above the other on the page. Down below they show how the beat results from the vector combination of the two.

Gaining an understanding of the sum product has proven more difficult. when I asked this question a while back in one of the sci.electronic groups, the responses were all trigonometry. I know that the formulas show that a sum product result, but I'm looking for the same kind of gut understanding that results from the nice graphs in the old textbooks.

Can someone help me with this? Otherwise I will feel comfortable only on lower sideband!

Thanks, 73 Bill N2CQR

Harry,

Well, unlike some people, Mike provided a "valid" email address.
I simply CC'd him on the posting. He mailed me back and the problem
has been fixed. If you used the above recomendation you could also
post with a valid email address. The spam filtered mail drop works
very well and eliminates the need for other spam blocking methods.

Martin

> results from the vector combination of the two.

Modulation is a different kind of process than beats. Beats involve the "sum" and "difference" of two signals in a "linear" circuit and modulation involves the "product" of two signals. A modulator is a "nonlinear" device or circuit.

The idea of AM is this: suppose we have a 100 watt carrier output from an xmtr, and suppose we increase the DC plate voltage on the PA. The increase in DC plate voltage causes an increase in the RF plate current that flows into the load. By that I mean that the increase in RF plate current is "proportional" to the increase in DC plate voltage. This is, by definition, a multiplication process.

Now, if we vary the DC plate voltage at an audio frequency rate, the multiplication process produces sum and difference frequencies (carrier freq plus audio freq and carrier freq minus audio freq), just as any multiplier would do.

A "perfect" multiplier will deliver only the sum and difference frequencies, suppressing the carrier frequency. In AM we modify the circuit so that the unmodified carrier power (100 watts) is not suppressed. In other words the 100 watt carrier is "added" to the output of the perfect modulator (multiplier). The additional sideband power is supplied by the audio amplifier. That is, the output power of the audio amplifier is added onto the 100 watt carrier power by the nonlinear multiplication process.

So to get an AM signal we 1) "multiply" the audio signal and the carrier to get the sum and difference frequencies (just like a mixer) and 2) "add" the carrier signal to the output of the multiplier. This is basically what an AM PA does, in fact this PA is often referred to as a "modulator", since that is where the modulation actually occurs.

We can (and do) also use integrated circuits such as the MC1496 to generate an AM signal. We generate a DSB, suppressed carrier signal, then add in the constant carrier, in the correct phase.

And of course the spectrum analyzer can separate the three distinct frequencies.

: my k-band gunn unit was a surplus police speed unit. no varactor. it is
: built from a solid block of copper (heat sinking). i modulate the gunn
: voltage with low level audio. for wide-band operation, this is fine. this
: likely wont work for narrow band, as the modulation voltage will reduce
: to microvolts, for 15khz bandwidth. the gunn noise will wipe this out.

However, if you bias the Gunn oscillator in the right region of
it's voltage/frequency curve, it is possible to use the wide bandwidth
to allow a large amount of loop gain in the phaselocked loop. With an
approriate reference, this lets the loop clean up the narrowband noise
and results in a pretty clean CW signal which can be modulated (FM)
directly in the loop or used with a mixer to provide arbitrary
modulation (I/Q).

An example of using a 10 GHz Solfan oscillator, without electronic
tuning, to produce an LO for 10,368 MHz SSB/CW is in my series of
articles "Designing a Station for the Microwave Bands". See Part 2 for
the Gunn oscillator loop details of finding the bias point as well as
a complete system for locking it with simple hardware and without
much test equipment.
The spectral plot in the article has too wide a span to show the
close-in noise which would be an issue with narrowband communications
but I can tell you that it worked very well for SSB. I still have the
transverter under the bench somewhere and the last time I turned it
on it still worked just fine.

The series was in 1988 Ham Radio Magazine which went out of print but
a web version of this is at:

In a multiplier, the output will change sign if either input changes
sign. (Because plus * minus = minus, etc.) Since BOTH inputs are
changing sign (because they're AC signals) the output will be changing
sign at a rate that is the sum of the two input frequencies. So, for a
1 KHz input #1 and 10 kHz input #2, so signal #1 has 2,000 sign
changes/second, and signal #2 has 20,000 sign changes/second.
Therefore, the output must have 22,000 sign changes/second, assuming
that there are no *perfect* coincidences of sign changes, which would
cancel each other in this analysis.

22,000 sign changes/sec ~ 11 Khz = freq #1 + freq #2. Not rigorous, I
know, but maybe it will help. (And it *does* get the right answer,
anyway.)

>To mix metaphors, you have to be real careful in the criticizing >business because sometimes you can open a real can of sour grapes.

Boy, when I get them wrong, I get them really wrong. It was not Wes's processor article that didn't have proper references. And I don't know how I got him confused. Duh. Maybe it was the ALC paper. Anyway, I owe Wes an apology.

I also neglected to add a few other sources that relate to audio processing and, perhaps, why the double-diode approach might not be the best choice:

"Communications Audio Processor for Reception," Don Hidreth, January, 1980, Ham Radio, pp71-79.

"Smart Squelch," Don Hidreth, June, 1983, Ham Radio, pp37-42.
"A Baseband Communications System, Part 1,"R.W. Harris and J.F. Cleveland, November, 1978, QST, pp 11-18.

"A Baseband Communications System, Part 2," R.W. Harris and J.F. Cleveland, December, 1978, QST, pp 14-21.

and, of course, Jim Fisk's review:
"Novel Audio Speech Processing Technique," Jim Fisk, June 1976, Ham Radio, pp 30-34.

An excellent article on why the Schreuer/Hildreth approaches work so well is found in:
"Do We Measure Damaging Noise Correctly?" P.V. Bruel, March-April, 1977, Noise Control Engineering, pp 3-10.

I am wondering whether this project makes sense. Swan 500 uses a 7360 tube as a modulator. This tube acts also as a clipper, and the clipped signal is filtered by the crystal filter. This is DSB RF processing which is better than any AF processing. In fact, with the Swan I had I consistently received reports 2S better than with the IC-735. On 80m, the Swan 500 was one of the first to get into DX lists. Copying weak signals was a different story because Swan's rx was poor. IMHO the best way to improve the Swan would be to add a preselector in the front and then a DSP in the back. Could cost more than the Swan is worth, though. But an AF speech processor could only make the signal worse.

Source record: 78581

Hello Renato,

Download program TANT136 from my website to design antenna tuning coil and
efficiency of a T antenna when tuned against a ground electrode system.
Down load in a few seconds. Not zipped up. Can be run immediatiately.
There's also groundwave long-wave propagation prediction program GRNDWAV2.

Rohde is no fan of using diodes at FET gates for stabilization.
In an article published in QEX several years ago, Rohde demonstrated
(via simulation) just how bad the diode was for oscillator purity.

I've personally become most interested in using an AGC loop to
vary the JFET bias, but I honestly don't know how well it compares
to precisely setting the bias by hand. It sure is a lot more
convenient for a VCO ;-)

3081. Re: Question: PVC for balun and coil forms.

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-09-30 00:00:00 UTC
From: Roy Lewallen <w7el@teleport.com>
Message-ID: <36127544.F6106419@teleport.com>
Source record: 78585

While I believe that PVC is adequate for most HF coil forms (at least in tubular form -- I'd hesitate to use a solid PVC core), it's certainly not a good idea to use PVC or any relatively poor dielectric as an insulator for a capacitor. In a capacitor, it encounters a large electric field, which results in the dielectric losses J L noted. The only really good common solid dielectrics at RF are polyethylene, polystyrene, Teflon (PTFE and FEP), and polypropylene. These are the only ones I'd use as a capacitor insulator, and for critical applications (like the capacitor in a small transmitting loop), even these might be noticeably lossy compared to air.

Roy Lewallen, W7EL

: to get fixed up with the metric system. It's the 'IN' thing.

There's a very useful DOS coil program that's "shareware" (but the "fee" is extremely reasonable. ;-) that does the calcs in inches, and in fact makes it very easy to calc for coils wound on standard US machine screws. It will give you parallel and series resonance frequencies and Q...all of which differ slightly from the values Reg's coil program yields. (Reg: I hope to do some tests to find out which is closer for one or two practical coils, but right now it's a very low priority for me.)

Junction fets like U310, P8000... are ok.
Mosfets/mesfets have this bad 1/f behaviour.
GaAs-Fets can have 1/f corner frequencies near 50 MHz.
The faster they are, the worse usually.

Bakelite is a phenolic, thermo-setting plastic. Have you tried
cyanoacrylate "super glue"?

Another note. According to Loctite information, their "Black Max 380 Rubber Toughened Cyanoacrylate" produced from 1-6 times the bond strength (depending on the formulation of phenolic) as their general-purpose cyanoacrylate adhesive. If standard super-glue doesn't do the job, you might try to locate some of this stuff. You might be able to get it from an industrial supplier.

Make sure that the surfaces are clean; Loctite recommends alcohol for cleaning phenolic.

>is filtered by the crystal filter.

I don't have access to the schematic for your Swan, however, if the 7360 is used *normally*, it is not clipping (limiting) either the audio input or the DSB output. The beam is being deflected by the LO (carrier oscillator) in a switching mode, in a fashion similar to driving a DBM with a square-wave LO. In either case, the output is *linearly* related to the modulating input.

>This is DSB RF processing which is
>better than any AF processing.

Clipping a DSB signal can be effective, but "better than AF processing" as a blanket statement isn't going to cut it in this group. Furthermore, when your DSB is filtered into SSB, all bets are off. Please read the references cited in my article and the references cited by the references, before you continue.

>In fact, with the Swan I had I consistently
>received reports 2S better than with the IC-735.
>On 80m, the Swan 500 was
>one of the first to get into DX lists.

Anecdotal evidence is proof of nothing. You may have had more power, a better antenna, a better location, better propagation or a weird call for all we know.

Using a modest 4 Yagi array, I've made a two-way SSB 144 MHz EME contact using my split-band processor, but so what. I wouldn't have made the contact without it, but then I wouldn't have made it without the 8877 amp, the GaAs FET preamp or any number of other things.

Anyone know of a good CHEAP source. I need at least four of them for an exposure box for my PCBs. Here in Sweden I have found a source but they cost $45 each plus SWE sales tax (MOMS = 25%). Duh!!! I also know of a source in the UK at about $20 each, but thata is still $100 including postage. Does anyone know where I can get them for a more reasonable price?

I also seek a UV tube for an EPROM eraser, but that is another story.

> ....how do you "pull" the frequency of
> does anyone have any ideas?

Yup! Try using two close spaced crystals of similar type in parallel
(i.r.o. 10 - 20Kz different). A bit of series inductance and a series
variable cap. If it "jumps" then you have pushed your luck with the crystal
frequency separation. Also try using the older/cheaper crystals since they
can usually be pulled more than newer crystals.

Harry

Source record: 78520

Hi,

I' m looking for a very low frequency radio transmitter/receiver application note (circuit diagram etc.) to build an underwater intercom to be used with my scuba diving buddy.
I know about existing devices like this that came out from scuba equipment manufactorers but they are very expensive.
I know that they all use 32KHz frequency and they range up to 50 meters underwater.
I would appreciate even information about low freq. radio or indications of some good internet site about this argument.

Thanks

Alex

Is the alcohol to clean the affected item or is it for the
owner/repairer as a "pick-me-up" after the stress & worry over whether
it'll actually
make a good durable repair ?? :-)

Alex,

This sounds a lot like the equipment being used by cavers for underground mapping and communication. I know someone is making kits for the ones that work at 180Khz. I don't have the info in front of me off hand, but drop me some E-Mail in a day or so and I'll try to have it ready for you.

I use blacklights that that are used by teen-agers to illuminate flourescent
posters and signs. They run about $15 in the U.S. and are fairly common.
Exposure times at two inches for circuit boards are 10 to 15 minutes. I
don't know if they are available in Europe. Any one else know?

I second the motion for "super glue". I have a Pavoni with Bakelite handle. Handle broke
and was repaired using the stuff. Handle receives lots of torque so I know it is good.

If the piece didn't break cleanly, I'd expect that "JB Weld" (comes in two tubes with
black white red coloring on package) would work well to fill in the joint areas. I use
it instead of epoxy 90% of the time.

I'll second Roy's suggestions...and mention that in the local Eagle Hardware I found some Loctite "plastic repair super glue"....it's a kit of gel superglue and an activator/cleaner you put on the surfaces before gluing. This stuff works well...I've fixed plastic eyeglass frames with it successfully, and they typically are not at all easy to get to hold together. Phenolic IS a plastic...it's thermosetting, not thermoplastic.

Another note: if the break is in a place that can be reinforced, try that, too. That is, if it's a flat surface, try putting some fiberglass (either raw glass fiber mat or a small piece of fiberglass-epoxy circuit board substrate) across the break, and glue it down with superglue. I've also fixed broken cylindrical things (like caps for bottles that were important to me) by wrapping tightly with thread or thin steel wire, and burying the wrapping in superglue. If you can find superglue accelerator, that can make life much easier, since with it the glue sets up in seconds, even in fairly thick areas. Otherwise, just be very patient, and don't test areas with your finger! ;-)

3109. Mic Mixer Homebrew - Please Help!

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-10-01 00:00:00 UTC
From: Dan Levin <djl@andlev_._com>
Message-ID: <3613c888.0@news.mediacity.com>
Source record: 78530

I have two 600 ohm impedence microphones (actually, a Heil mic and a computer sound card) that I want to connect to the input of a single radio at the same time. I am told that I need a mixer to do this. "Real" microphone mixers seem to cost a fair bit - but I found a small mic mixer from Hilton ($35) that looked perfect. Unfortunately, the Hilton mixer is for "high impedence" mics, and it turns out that 600 ohms is not high impedence :-)

I opened the thing up, and it is just a resistor and some kind of variable resistor (?) in series with each mic input - then the outputs of the variable things are tied together.

Only one problem. My EE skills were never very good, and they are now 20 years rusty... I can still solder, but I can't do math :-)

Can anyone tell me:

1) What are these variable things? They look like pots (variable resistors), but they have three leads, not two. In this Hilton thing, one lead goes to ground, one goes to the hot side of the mic input, and one goes to the hot side of the mic output (tied to the same pin on the other variable whatever it is).

2) What size resistors I need to do this? Looks like I need a fixed resistor in series with each mic input, followed by this variable thing. I need to know the resistance an/or other features of both the fixed resistor and the variable things (resistors?), given that my mics are 600 ohms.

Thanks a million. Any other hints or tips most welcome.

HO, HO, HO.

I do think if yo are gonna use alky on the phenolic you shold try to use
anhydrous alky or at least 91% alky. The usual drug-store 70%
rubbing alky is likely to work poorly.

My experience.

To get anhyd alky, we had to buy a doz bottles, but they had 91% on
the shelves.

3111. Help--convert 500khz to 455khz IF?

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-10-01 00:00:00 UTC
From: cjg2@concentric.net
Message-ID: <6v0lkh$28l@chronicle.concentric.net>
Source record: 78532

Could anyone point me to a QST article or info on a circuit that will convert a 500khz F signal to 455khz?

What I'm trying to do is build an outboard product detector and IF strip for a couple older receivers. Since the filters I am using are 455khz (as well as one of the radios this is being designed for use with), and one of the radios uses a 500khz IF, I need to build a converter to change the 500khz output of the receiver to 455khz.

Specifically, the circuit will have a Vin (500khz) of .2 to 10Vp-p, Zin of about 70 ohms. Output (455khz) will have a Vout of a few volts at either low or high-z.

Thanks for any help figuring this out--I'm new to rf!

The best glue for bakelite is sold as a waterproof wood glue. It is a 2 part system consisting of a powdered resin and a liquid catalyst. It contains resorcinol and formaldehyde, which are pretty nasty chemicals, so use with care! Bakelite is a polymer formed from phenol and formaldehyde, so this might explain why this stuff seems to work so well! Regular solvent adhesives will not soften bakelite, so they won't bond very well.

3115. Fixing HP355 attenuators?

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-10-02 00:00:00 UTC
From: mike czuhajewski <wa8mcq@erols.com>
Message-ID: <36145463.3460@erols.com>
Source record: 78438

I bought a few HP355C and HP355D step attenuators at a good price, as-is, hoping to find a few good ones and fix up the rest. Three guesses what the ratio of good to bad turned out to be :-) (At least one of each was good, though.)

I put them all on one of the HP 3753C network analyzers at work and saw some really wild sweeps on some of them. It's obvious that the resistors are all OK, not fried, but that some of the DPDT microswitches are flakey at best--dirty contacts or just plain dirt, period. There are some effects seen on the sweeps that make it appear that there are a few parasitic capacitances floating around inside some of them, ie, odd frequency related effects that cannot be otherwise explained; again, probably inside the switches since visual exams of all units show nothing out of the ordinary, and all are squeaky clean under the covers.

Here's the question--has anyone had any luck with fixing the HP355C and D attenuators? Are the microswitches, which are controlled by cams on the shaft, plain-Jane, run of the mill microswitches, or are they high performance types? I haven't called HP yet and prefer not to, since I suspect I'll get one of the standard answers--"buy something newer" or "we cannot condone use of anything except genuine HP replacement parts" :-)

(Both models are frequently seen at hamfests, usually selling for far more than I paid for these. They're rectangular with a rotary knob on the end. The HP355C goes from 0-12 dB in 1 dB steps and the HP355D does 0-120 by 10 dB steps. Interestingly enough, this venerable model is still available from HP, or at least it was still in their catalog last year.)

BTW, a few years ago I had an old Kay Electric step attenuator that had an intermittent switch. It's one of the older models with toggle switches. I called Kay and they wanted $47 per switch (this was circa 1992) although that also included the resistors that went with the switch. I chose to drill out the rivets from the square, teflon body of the switch, clean the parts inside and reassemble with long 2-56 screws. Worked like a charm, and considerably less than $47!

3117. List of the rec.radio newsgroups

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-10-02 00:00:00 UTC
From: jeffreyh@Hawaii.Edu
Message-ID: <6v1m4l$50a@news.Hawaii.Edu>
Source record: 78440
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew

```
Archive-name: radio/personal-brief-introduction

In an effort help ensure a poster's article reaches the appropriate
audience, below is a list of the rec.radio newsgroups. In most cases,
a group's name will explain its purpose. Cross-posting should rarely
be necessary.

rec.radio.broadcasting (devoted to the broadcast industry; moderated)
rec.radio.cb
rec.radio.info (periodic informational bulletins; moderated)
rec.radio.scanner
rec.radio.shortwave
rec.radio.swap (for buying, selling, and trading; not a discussion group)

rec.radio.amateur.antenna
rec.radio.amateur.boatanchors (tube-type communications equipment)
rec.radio.amateur.digital.misc (packet, pactor and other digital modes)
rec.radio.amateur.dx (long-distance amateur communications)
rec.radio.amateur.equipment (questions, comments regarding commercially-
built amateur gear; not for buying/selling)
rec.radio.amateur.homebrew (devoted to home-building ham gear)
rec.radio.amateur.policy (issues include code, restructuring, local
restrictions in conflict with FCC R&R)
rec.radio.amateur.space (satellites, meteor scatter, EME)
rec.radio.amateur.misc (any topic not covered in the above groups)

(At least two other English language radio hierarchies exist, prefixed
with "uk" (United Kingdom), and "aus" (Australia), in place of "rec.")

Again, cross-posting should rarely be necessary. Many times, a long-
running thread results from a single cross-posted article, and the
contents of such a thread drift further and further away from being
"on-topic" in the various NGs that receive each and every followup.

For more detailed information, see "Guide to the Rec.radio Newsgroups"
posted on the 15th of each month.

Well, Tom, here we see once again the oppression inherent in typing in ALL CAPS.

Of course, since it is indicated as an amp(lifier) one might guess at the input/output relationship.

GIGO comes to mind.

Sincerely,

Gen. New Micros

> D attenuators?

Yes, actually, in the case of a 355D purchased at a hamfest for $10 last year. I took it home and swept it, and it seemed basically OK except for a rise in insertion loss around ~300 MHz -- on the order of several dB if I remember right. I don't remember exactly where the dip was or how deep it was, but it was somewhat puzzling as the DC resistances of all the internal resistors and switches checked out fine. (This was at the 0 dB attenuation setting, so the resistors shouldn't have mattered in any event.)

I eventually tried placing a temporary coax probe at each successive switch approaching the input BNC jack, and found that the dip seemed to be occurring at the input jack itself. I tried fiddling with the capacitive stub at the jack termination, but it had no effect on the problem. Replacing the jack got rid of the dip altogether.

Visually, the "bad" jack looked just fine. I don't know what could go wrong with a BNC jack to demonstrate what amounted to a series-resonant effect like that, but it was definitely the problem!

There were no other complications -- I went ahead and replaced both jacks for good measure, and found the insertion loss increased fairly linearly with frequency to 1 dB at 1.33 GHz, which is well within the HP catalog spec (1.5 dB at 1 GHz.)

I don't have a way to sweep its VSWR or phase shift, since I don't have a vector network analyzer, but the magnitude of the attenuation was safely within specs on every range down to -90 dB or so, beyond which I couldn't measure with my test setup (Tek 492 w/homebrew tracking generator, maximum output level=0 dBm). I'm satisfied that it's basically in good shape, and at any rate it's hard to nitpick for $10 and the cost of a couple of new screw-in BNC jacks.

Hopefully the switches aren't the real problem. They are definitely not
standard MicroSwitch(tm)-brand microswitches. I don't know how tightly
they're sealed -- a shot or two of tuner cleaner around the external
terminals might make it through to the contacts. Have you measured the
resistors?

Hi Mike -

The switches may not be dirty, but instead there may be problems with
how the cam actuates them. There are little pieces of plastic between
the cam and the switch levers - if any of these are broken or shifted,
you'll get incorrect dB steps, or, if the switch 'almost' closes, you'll
get capacitive coupling effects, which might explain your wild sweeps.

(I once purchased one of these attenuators at a swapmeet and later
discovered at home that two of these plastic pieces were broken. Bit
of a pain to fix it!)

72,

- Jeff, WA6AHL

3122. Big meteor shower November 17-18th, work some meteor scatter DX on VHF

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-10-02 00:00:00 UTC
From: wa2ise@netcom.com
Message-ID: <wa2iseF06n0I.1L1@netcom.com>
Source record: 78445
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew,rec.radio.amateur.misc,rec.radio.amateur.boatanchors,rec.radio.scanners,sci.astro

On November 17 and/or 18th, before dawn in the wee hours of the morning, the leonid meteor shower is expected to hit big time. And thus opportunity to do some long distance "DX" communications on VHF and UHF frequencies. These radio waves can bounce off of the ionized meteor trails in the sky. Could be thousands of meteors per hour at the peak. With this many meteors, one might be able to carry on long QSO's (radio conversations). One could monitor FM broadcast band stations of distant cities to listen for "openings". Or NOAA weather freqs.

And we can still do this even if clouds cover the sky.

Well, first of all you have to realize that the PA is acting as a mixer. In
Class C, the PA is switched on and off at the carrier rate. Thus it is a
non-linear device and can behave as a mixer. The products of the carrier
and the modulating frequency can only be expressed properly using trig.
The key to understanding why there are two sidebands is in realizing that
the cosine of the carrier changes signs every half cycle. So you get plus
and minus sidebands at a sample rate of the carrier. You can think of this
as a sample and its alias. The PA tank acts as a reconstruction filter for
these samples so the output consists of clean analog mirror images of
the modulating signal translated in frequency from the baseband to
frequencies symmetric around the carrier frequency. Since the PA isn't
a balanced mixer, you also get the carrier passed through, so you have
DSBWC AM.

>
><<But wait, where does the *difference* come from? :-O >>

What you're missing is that the carrier changes sign *many* times
for every sign change of the modulating frequency. You can think of
this as a sampling process. You wind up with a sampled signal and
its negative, ie sum *and* difference. The PA tank circuit then acts
as a reconstruction filter and smooths these samples back to analog

signals which are mirror images of each other, symmetric around
the carrier frequency.

> Crazy glue does great. I back it up with epoxy(scrape surfaces well).

I've used Crazy Glue on Bakelite parts with very good results after cleaning with detergent and water and then 91% isopropyl alcohol. I dried the parts at room temperature first and then for a few minutes in the microwave oven to be sure any residual water was gone before applying the glue. Don't use the microwave with parts that have metal inserts.

I've also gotten good results with epoxies. Clean as above and use the slow setting variety of epoxy. Let it set for a day or two at room temperature and then put it in the microwave for several minutes at a lowest setting until quite hot to the touch. Don't rush the room temperature curing or you'll get bubbles in the bond. I've edge-bonded .125" sheet stock this way and it was surprisingly strong.

>amplitude modulation found in every text book. This is that the carrier
>varies when we look at it in time but does not vary when we look at it
>in the frequency domain.

That's simple. You can't view *just* the carrier in the time domain. All you can view is the vector sum of the carrier and the sidebands. That vector sum does vary with modulation. In the frequency domain, you *can* separate the carrier and the sidebands, so you can see that the carrier doesn't vary in amplitude with the modulation.

The sidebands may not vary in amplitude either, if the modulation is a pure tone. But the vector sum of the carrier and the sidebands will vary as a function of time because you have to have terms in the sum to account for the phase rotation of the two signals as a function of time. Those terms are at different rates for the carrier and the modulating signal.

So in the time domain, we see only the result of summing those different rates as a modulation envelope. But in the frequency domain, we see the separate vector components as functions of frequency, steady and unvarying in amplitude. We don't see the vector sum, the modulation envelope, because that's a function of time, and we're looking at a function of frequency in the frequency domain.

Both views show us what is really happening, but they look at what's happening from different perspectives. The time domain shows us the vector sum as a function of time, but can't show us the individual components of the vector sum, which are in the frequency domain rather than the time domain. The frequency domain shows us the individual vectors as a function of frequency, but can't show us the vector sum because that's a time domain relationship and that can't be displayed in the frequency domain.

Which view is true? Both are, but the frequency domain view is more fundamental because the vector sum which is the modulating envelope is a *result* of what we see in the frequency domain. In other words, the whole is the sum of the parts, but we can't reverse that and say the parts are the result of the whole. The relationship is anti-symmetric, or in other words, we can't reverse cause and effect.

GE germicidal lamps are the lowest cost shortwave UV tubes I've seen.
These are 8 watt appliance lamps. Check with your GE distributor for cost
and availability. (They cost about $8 from GE distributors in the States.)

If you want to "scratch" a xtal radio, get yourself some Galena (lead sulphide) from a chemical supply house and crunch it up into little pieces. This is the material used for detectors in the original crystals sets. Most encylopedias will give you a basic circuit, consisting of a tuned circuit, detector, and hi-z headset connected to an antenna and ground.

I still have a small quantity of these items left. $35 each post paid conus or 10 for $300 post paid conus.

For Sale: Vectron 718Y2828 10 Mhz Oven Controlled Crystal Oscillator. New mfg. Power 12VDC, output 5volt P P sine wave into HI Z load. Very small package, ~2"X2"X1" power connections solder pins, RF out SMA, mounts via 4 studs on bottom of package. Delta Frequency adjustment available via screw driver adjustment. Vectron data on 718Y2828 indicates 2E-8 aging rate per year and 2E-8 stability over temperature range. Measurements on my HP 5370A with HS option clock confirm the stability, Unit consumes about 150 MA upond application of power and then drops off to around 75MA after warm up. With hookup documents, $35 each or $300 for 10 post paid conus.

Post Paid conus.
Tnx for the read es 73

Hi all, I am looking for a design to make a interface to program
Motorola radio's. I have made a RS232 to TTL interface that will
program a Motorola GP300 and also a GM300 OK. But on these
radio's you only need GND and DATA to program them.

I Have a Motorola HT1000 that needs GND, Busy and BUS+ etc.

If you have a design for an interface to program these radio's
please E-Mail me a copy......Thanks.

Oh yes, by the way, have you seen my Web Page ????

The address is:
http://ourworld.compuserve.com/homepages/colinlowe

On this page there are mods for GP300 and GM300. Also Kenwood
TH48 and TM732. Also The new Yaesu FT847 etc.

How close to "scratch" do you want to get? When I was a Boy Scout,
I came up with a crystal set design that we could build for
essentially no money. We even made the tank capacitor
from layers of aluminum foil and an insulator. I think we built
about 300 of them in one day as a Scout Show attraction.

Send me your snail-mail address via e-mail if you'd like more
details.

Regards,

Brian

I've had some time to go over the code and comments concerning the PLL2002 based scanners, a couple of items bother me, 1) comments say that the first 8 bits of the N packet are always low, the data file listing sets them to 24h, why? 2)ahow is the R register value computed, I have found where the N value is computed, but can't seem to find any info on the R value except for the two presets.
I REALLY got a lot out of your posting otherwise. I cracked open the case on my RS scanner and found a '2002 inside, after seeing a lot of folks saying "there are no modifications" available for the unit I think this will change things...

Looks like a very nice piece of work; probably should've used a few more screws on that power supply's front panel, though. :-)

Unfortunately, when you post a picture to a non-binary Usenet group, it gets physically propagated to every news server on the planet that carries that group, including servers that aren't intended to support the load of binary groups. Additionally, since lots of people download message traffic to read offline, it can waste a lot of bandwidth on the client side as well. Better to store the image file on a single site and post a link to it on the NG, with the http:// prefix so that everyone's browser will show it as a clickable hyperlink. That way, those who want to see it can easily do so, and the bandwidth-challenged won't have to deal with it.

Another way to look at it is that in order to look at things in the
frequency domain, you have to trade out your resolution in time for
resolution in frequency. In order to see things in 1 Hz resolution,
you have to look at things over a duration of 1 second.

You're not really seeing a constant carrier over this sample duration,
rather that there is a constant amount of energy at that frequency summed
over that entire period.

The constant carrier is an artifact of the 1) measuring instrument or
2) the math. Take your pick, all comes out the same.

Ignore the AGC line. It's not needed and comes into play only on
strong signals which you rarely encounter.

The TV-R7100 will work fine on the R7000 by just leaving the AGC line
floating.

3149. HELP Surplus Generator Manual Needed

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-10-03 00:00:00 UTC
From: Stuart Cole <stuartac@earthlink.net>
Message-ID: <3616A66A.36CDF6F0@earthlink.net>
Source record: 78393

HELP!

I AM APPEALING TO ALL HAMS WHO MIGHT HAVE PROCURRED A 10KW GENERATOR
THRU THE MARS SURPLUS PROPERTY PROGRAM OR THRU A SURPLUS SALE.

THE GENERATOR IS A MODEL 4A084-III FSN 6115-00-889-1447
THE TECHNICAL MANUAL IS TM5-6115-275-12

THE GASOLING ENGINE IS THE SAME MODEL AS THE GENERATOR AND THE FSN IS
2805-00-872-5972. THE TECHNICIAL MANUAL IS TM5-2805-259-14P &24P.

I NEED THE TECHNICIAL MANUALS FOR BOTH THE ENGINE AND THE GENERATOR
I WILL BE WILLING TO PAY COPING COSTS. PLEASE EMAIL IF YOU HAVE EITHER
MANUAL.

THANKS

EMAIL STUART COLE, N5LBZ AT scole@juno.com

US Army Signal Corps Transmitter Tuning Unit TU-5-B. Frequency range - 1500 - 3000kc. $75.00 plus shipping. Unit is in almost perfect condition and has a 1943 serviceability tag signed etc. attatched to it. Inside is like new. This unit makes use of a National velvet vernier drive, and a right angle drive. The settings window, information card and plastic are like new. It appears capable of handling a fair bit of power. I forget the specific transmitter the unit is meant for, but these items were popular amongst hams after WW2.

Thanks to those who have responded with this answer. That is what the
previous owner told me. I just believe that the unit will work better
under all circumstances if the AGC is hooked up.

Unfortunately, the peak won't be visible from the US. The radiant of
the Leonids is out of the constellation Leo, of course, and that won't
be above the horizon for US amateurs during the peak of the shower.
This is supposed to be a 33 year peak, and counts as high as 100,000
meteors an hour have been predicted, but we're going to miss the
show.

Since the peak will be below our horizon, we can't take advantage
of it for meteor scatter contacts either. Sorry. Maybe in 2021.

>

Fiberglass behaves very well in strong RF fields and is used as pressure windows in wave guides. I am not familiar with the polybutal. I have also noticed while attempting to use PVC as a support for a vertical that it had the effect of making the antenna tune up a good bit lower in freq than a fiberglass pole did.

I am not sure of what you are saying. It appears that you are are assuming that when looked at in the time domain that there can only be one frequency present at any given instant in time. This is not true and I know of no credable source that says it is. The output of an AM mixer will contain the sum and difference frequencies along with the origional components and a large number of other products, most of which are eliminated by filtering. The frequency of the carrier is never changed but other frequencies are created in the modulation process.

If you could look (using an oscilloscope) at a single cycle of an AM modulated signal, and compare that with a single cycle of an unmodulated signal, you would find that the modulated cycle is slightly distorted and is not a perfect sine wave, like the unmodulated signal. Since it is distorted it contains more than a single frequency. These other frequencies are the sidebands.

As a long-time meteor jockey (first QSO July '74) I can say that the
predicted "peaks" are often (always?) wrong.

These predictions are "precise" measurements of almost random events.
We have a cloud of debris in orbit around the sun and because 33 years
ago, and 33 years before that, we had big showers doesn't mean that an
exact day and time for recurrence is predictable.

Persieds used to have a *peak*, then it had two, now it has three and
every time I've set schedules for the "optimum" time, it happened
yesterday or tomorrow. This is another example of the danger of
computer programs. Somebody's program predicts the optimum and by
god, that's when you have to make your schedule.

I can't wait until some program predicts an *optimum* frequency too.
"Joe Blow's program says 144.12345 is the optimum for the Flakids
shower, so I'm making all my skeds there." And so is everybody else.

Bah. And what has this to do with antennas anyway?

N7WS

Yeah, but the best way to injection lock a maggie is with a probe in one
of the cavities. That requires modifying the tube, and pumping the vacuum
back down. Most of us aren't equipped to do that.

I want to use an ICOM TV-R7100 (TV demodulator) with an ICOM R7000. This unit is almost identical to the TV-R7000. The TV-R7100 has a chip added for FM stereo and an AGC line that connects to a R7100 or R8500 receiver. I would like to get a schematic for the TV-R7100 and a partial schematic of a R7100 or R8500 showing where the AGC ties in so I can attach the TV-R71000 AGC line to a similar point in my R7000. Any help would be appreciated.

Thanks,
Dick

Hi,
I,m looking for any information or links to documentation on the YAESU FT767GX CAT system.

I am currently learning C++ and Assembly language for the Intel processor and thought that attempting to control my dusty old radio by computer would be a great way to revive my interest in amateur radio.

So, if anyone knows of any sites with relevant info please let me know.

Thanks in advance

Mike

Hello Larry,

That's a tuning unit for the BC-191/375 transmitter. It was teamed with the BC-348 receiver in most USAAF heavy bombers (B-17, B-24, etc., but not the B-29 - they got AN/ART-13s). They were also used on the ground with BC-342 receivers.

It's very likely that I've missed something here.

According to my SkyGlobe program the constellation lLeo will be about 15 degrees above the horizion starting at about 1:30 am on Nov and it will "set" (read drop below 15 degrees) at about 12:30pm (EST). The same is true for Nov 18.

Must we be able to see the meteor trail to work a contact?

Even if the shower won't be at it's peak here in North America when leo is up, I wouldn't expect it to be a step function (ie 100,000 meteors/hr...click...0 meteors/hr).

As I understand how this meteor shower thing works: the movement of the Earth in it's orbit around the Sun will cause us to pass through a cloud of space junk. On Nov 17,18 we will be moving towards the constellation leo.

While I'm thinking about this I see that the constellation leo will be down for *about* 12 hours. It is this 12 hour period which I would expect to be the peak of the shower. Being as how it's the middle of the shower. With this bit of reasoning, I would expect our (North American's) best shot at the Leonids will be on the moring of the 18th.

As I look at the constellation of leo, it's only about 25 or 30 degrees wide. How wide will the cloud of junk be as we pass through it? Seems like it must be larger than the whole Earth (180 degrees plus) or we would hoover up all of the meteors the first time we passed through the cloud.

Let me just say that I've never worked even one meteor contact so I clame NO expertise on this subject. It just seems that the rational may be a little bit flawed. No insult intended here! If I'm wrong please tell me so, and why.

Thanks

Er, Yes. I have to scrape around and find substitute tubes, circuits, string, etc because I have not been earning for a few years. I find the discussions, tips, hints on these groups very helpful. I also learn a lot of "abstract" stuff like it's silly to use 6L6s just at the moment; but I know there are 101 tubes I can use instead, which have not been laid upon an altar by hi-fi magazines.

And suchlike.

Hi: I have a bunch of crystals I'd like
to trade for the following FT-243 types:

I need any freq between 5000kHz and
5300kHz, and any CW frequency.

I have for trade the following in the
small HC-6 (?) holders:
148.88, 164.665, 156.80, 121.80, 39.00,
160,20, 154.31, 162.40, 33.89, 44.96,
460.05, 42.52, 45.85, 45.62, 45.70,
430.02, 462.95, 45.60.

And in the larger HC-25 (?) holders:
15877.5, 16377.5, 16177.5, 15777.5,
8777.5, 6.755, 16277.5.

Thanks!

Bob, W1CNY

I have a Jennings Vacuum Variable, about 0.1 to 60 pF, 20,OOO volts. You can see a picture of it at:

http://www.iaxs.net/~gfbike/vacvar.jpg

There is no evidence of any heating of the plates and the operating mechanism is fine. It is 5 inches long (including shaft) and 3 inches diameter at widest point.

Just what you need for that high power amplifier for 20 meters and above!

$200 OBO

I'm still spending money on it, so I better be enjoying myself.

Seriously, I just bought my first HF radio, a Ten-Tec Scout. I
consider it motivation to upgrade, since with my Tech + licence
is a bit short in the HF privileges.

Today I built my first antenna, a long wire approximately 150 ft long.
Tomorrow I contemplate a 10m vertical. This to give me something
to do on the air while I try to relearn enough code to be
intelligible.

Am I enjoying myself. I don't know, I am too busy to notice. :)

Source of 8 Microfard 450 Volt Electrolytic Capacitor in UK?

Does anyone know where I can obtain the above item? I would prefer new, as old electrolytics tend to lose their capacitance due to drying out.

I have looked in the Maplin, Tandy and Mainline catalogues, but no luck.

Thanks

>Must we be able to see the meteor trail to work a contact?

No. We can get meteor trail propagation just as well in daylight as at night.
The "light show" is only visible at night of course.

>Even if the shower won't be at it's peak here in North America when leo is up,
>I wouldn't expect it to be a step function (ie 100,000 meteors/hr...click...0
>meteors/hr).

True. But the shower is supposed to be sharply peaked. At least it was the
other recorded times we passed through the heavy clump.

>As I understand how this meteor shower thing works: the movement of the Earth
>in it's orbit around the Sun will cause us to pass through a cloud of space
>junk. On Nov 17,18 we will be moving towards the constellation leo.

It is sort of like a bullet hitting a bullet. The Leonid meteors are screaming along
in their orbit, and Earth is trotting along in its orbit. The two orbits intersect,
naturally, or we wouldn't have a shower. The debris cloud is not evenly distributed
about its orbit. Most years the Leonids don't put on much of a show. But there are
a number of "clumps". The largest clump is the one we'll intersect this year, and is
the same one we intersected in 1799, 1833,1866, and 1966. (Timing is everything.)

>While I'm thinking about this I see that the constellation leo will be down
>for *about* 12 hours. It is this 12 hour period which I would expect to be the
>peak of the shower. Being as how it's the middle of the shower. With this bit

>will be on the moring of the 18th.

The prediction is that the peak will occur over the Far East Pacific. Of course
it will be well below our horizon at that time.

>As I look at the constellation of leo, it's only about 25 or 30 degrees wide.
>How wide will the cloud of junk be as we pass through it? Seems like it must
>be larger than the whole Earth (180 degrees plus) or we would hoover up all of
>the meteors the first time we passed through the cloud.

The figure I saw said that the cloud diameter is about 300,000 miles, which makes the time to pass through it about 5 hours. Peak is estimated to be near the middle of that period. By the time North America is on the leading side of the Earth, the shower should have come and gone.

As Wes noted, prediction is an inexact science because gravitational resonances, mainly with Jupiter, can alter the debris clump from one orbit to the next. But this is the best estimate available.

there is always leeway with MS contacts and showers. predicted peaks are good for predictions. so, getting skeds is one way to insure "something". another way is simply listen on 6 or 2 meters, pointed at the radiant. i did that a few years ago, in seattle, during the perseids. heard pings for several hours, and a couple of 3 and 4 second bursts. i managed a partial contact, the other end died out as he replied with his grid square. darn...

better reslts are had with lower freqs. i've read (in older QST issues), during sunspot lows, that MS contacts can be had even on 20 meters.

I got my licence in 1962. Have been active for 3 years and then the kids, the job, the travels forced me to stop.I retired early with one objective in mind...get beack my license and experiment again with what can be experimented in today technology by a simple technician. I then restarted two years ago focusing on antennas. Now I believe I understand 10-20% of them but anytime i make a QSO and talk about my experiments, tests,achievements and disappointements and I exchange my technical views, I get a lot of attention and many OM's express their satisfaction in hearing QSO's talking about technical experimentation against the many QSO's just talking about the weather.....
Our hobby should get back to its initial objectives and this will by sure attract lot of yungsters.

All the best Anselmo, HB9ICK- IZ3BGJ

Folks,

Just yesterday I ran into one of those things that give newcomers the impression that HAM radio operators can be elitist and exclusionary -- I was on the 14,247 kHz DX net on 20m, going through the rotation as usual when I got really slammed by one of the net control guys -- just for giving the DX station my name and QTH! It wasn't as if I was conducting an extended rag-chew QSO either -- The whole thing was over in less than 30 seconds. Apparently, it is only acceptable to give call signs, signal reports and 73's to DX stations on the DX net. Nevertheless, the language and tone in the rebuke was so completely out of proportion and uncalled for that I won't repeat it here. I have only been back in amateur radio for a month (after a 25 year hiatus), and it really gave me a cold feeling to think that other people just getting into HF might get this kind of treatment as well. People have to remember that lives don't depend upon the procedures used to work DX... We should be working towards maximizing the cooperation and pleasure of all amateur operators, or else we're all going to lose out. If I hadn't known that this was something of an aberration, I would have developed a bitter feeling about ham radio in general and HF in particular. As it was, it soured the experience for the rest of the day. I realize that nerves were a little ragged due to the QRM problems stemming from the California QSO Party, but that doesn't excuse rude behavior that is detrimental to the hobby as a whole.

Really. The old stuff is rugged. Almost everything electronic made today is made to be thrown away. There don't make like they used to.

>Oh, and anybody who's ever soldered knows it's *not* something one does
>naked!

Tried it once or twice. Those splatters find their way to the most unusual places...

3200. Q: Help Identifying 915Mhz TX/RX Modules

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-10-04 00:00:00 UTC
From: qsccbcnc@gis.net
Message-ID: <6v8ehmgkr1@supernews.com>
Source record: 78423

I found a Uniden Model #EXP9100 Spread Spectrum Cordless phone in the trash. I stripped it and found two really neat modules in there. I suspect that these are tranceiver modules. They are shielded in plated plastic and have a little ceramic thing next to them marked 915M. I think it's safe to assume that this means 915 Mhz. They have a marking on the circuit board that says GCMK-G2X. They are terminated in a 12 pin inline connector which pluged into a motherboard with two large chips on them with Uniden house markings. Probably a microprocessor. Are these reusable? Is there anywhere I can get pinouts for the connectors? I would like to use them as a low power RF modem/data link. Thanks for any help.

-Ming

Yeah but joining a 'LIST' to get to work a DX station through an intermediary
self-styled "RADIO GOD" like that is no fun anyway.

How BADLY do you want to work a new country?
If it means licking that bastards jack boots, I don't NEED to work the stinking
DX! I would rather wait and take my chances to work the DX the REAL way.

Some of those "DX NETS" with a control operator, sound as phoney as the County
Hunter QSOs where each station imagines they gat an RS "2-2" report from the
other guy and the relay station confirms it as a good QSO where in actual fact
they can't even hear each other at all!

HELLO? "SEVENS COME NOW - BEGINNING WITH ALPHA ONLY!!"

BC-191 or BC-375
The TU units sold for about 50 cents each in the 1950s and 60s.

We all need those 50 pF and 100 pF variable caps with no shaft.
Best part in 'em is the ceramic rotary switch which you can use
as a bandswitch in that homebrew medium power linear if you
really want to spend $75 for a switch!

They still show up all the time under the tables at hamfests and can be had for
about $10 tops.

Funny you should mention that. I've been very quiet on 2 metres in the
UK for many years but in July I was near Kendal on holiday and thought I
would ask after an old G3 friend so I made a short call through the
local repeater.

Three people came back to say that you get funny types using the repeater nowadays, who haven't paid lately.

In spite of stories about Scottish parsimony, I think it is safe to say that passers by are VERY welcome to use Scottish 2 m repeaters and are not expected to pay.

Evidently the comradehsip we have been used to in amateur radio is no longer all-pervading. Now get off my bandwidth.

3210. President Lincoln and HR-2600 question

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-10-04 00:00:00 UTC

Message-ID: <18576-36181550-2@newsd-113.bryant.webtv.net>
Source record: 78433

I was wondering if anyone knows of a dealer or ham radio company that sells the President Lincoln 10 Meter mobile radio, or any of the other 10 meter rigs that President makes? I thought that President was primarily a European company now, but my brother says he has seen some of their radios sold here in the U.S. I can't find a U.S. telephone number or address on their web page, and I was curious if President or Uniden is going to get back into the manufacturing of 10 Meter mobile units now that 10 meters is starting to open up again and more people are wanting to get back on the band. Also, if anyone knows of a company that may be selling un-opened HR-2600's "new" in the box, please send me an e-mail and let me know. Thanks!

73,
M. Brown KU4UV

I just got in to the hobby, not on the air yet but I passed the no code tech tests. and am waiting for a call sign.

I got an HT and have been using it as a scanner and listening to the nets on 2 meter and 70 cm. I'm looking at a booster for the car and further down the line a base or repeater at home, that is far off though.

What is a wize detector and how does it work? See
http://www.intio.or.jp/jf10zl/2trfm.htm for a schematic of it... Never
seen it before, and can't find anything similair in any of my books... TIA

Can you import such parts to UK? Check the Digikey website
(www.digikey.com). They are always a good source of parts.

Good bet it's an LA1201, in the ECG/NTE series as ECG-1003, a 4 stage IF
amp.

This will work but don't expect as much output as you may
get from a similar 3CXxxx tube. The best way is to apply the
proper grid bias even if you are operating the tube in grounded grid.
You don't want any control grid current but you do want the
peak plate current you would get if the tube was properly bias and
operating in class AB1 mode. This will happen when the control grid is
at zero volts, which is in your proposed connection, and the screen
grid is at its normal operating voltage around 300 volts or more.
This means you need a peak drive voltage of 300 or more volts. This
would be over 200 watts if you connected directly to the cathode
and had several tubes in parallel. It may work better good impedance
matching but I just don't know what the input Z is for such a circuit.
A friend of mine was experimenting with GG connected 4cx250's 30 years
ago and had little success with it. Including the circuit you suggested.
However he may have been trying to drive it with out a matching network
and thus did not have enough drive. I may explore it again sometime.
Please let me know how it turns out.

Jim,

>I saw a vague diagram of an amp using the 4CX line of tubes in the grounded
>grid configuration. The screen was grounded and the grid was tied to the
>cathode. I am looking for design info and schematics on this type of amp.

The 4CX250 can indeed be run GG, but the screen and grid need to be
at ground for RF via bypass caps and at normal bias and screen
voltages....not grounded for both RF and DC!

Some tubes can be run GG with grid and screen at both DC and RF
ground,
but the 4x/4CX 150, 250, 300, 350 etc need normal voltages. Both
the ARRL handbooks and the Radio Engineers series handbooks
contain several examples of GG linears which can use the 4X/4CX
tubes. Check in the VHF/UHF sections.

I have started a business that produces low cost, precision-made PC boards for hams/electronic hobbyists using their Gerber/NC Drill files.

In addition to my print advertisements I would like to advertise in newsgroups to attract the most attention yet avoid conflicts with the intent/purpose of newsgroups such as this. I really don't want to get flamed for placing what could be perceived as crass advertisements in newsgroups. Are there "favorite" newsgroups that people in this forum would visit to learn about new companies and their services?

Thanks and 73s.

I have the service manual for the radio shack ET-926 (cat # 43-1096).

I doubt this is the same phone, but from reading the parts list I'd
guess the part you have marked 915M is some sort of filter and
on the schematic on this phone is fairly close to the antenna.

>They have a marking on the circuit board that says
>GCMK-G2X. They are terminated in a 12 pin inline connector which pluged into a
>motherboard with two large chips on them with Uniden house markings. Probably
>a microprocessor.

The radio shack phone has one ASIC (?) which handles the keypad
and has I/O lines labeled tx-pcm & rx-pcm. Looks like almost
everything goes on there, except the A/D & D/A is a separate
chip. Oh the "ASIC" has a "sleep" pin so it's probably a
micro too... [100 pins].

Some of the other chips look like:
- serial eeprom
- pll synth
- rf input mixer (both I & Q channels)
- rf output
- linear power regulator

> Are these reusable? Is there anywhere I can get pinouts for
>the connectors? I would like to use them as a low power RF modem/data link.
>Thanks for any help.

I don't know how hard it would be to get the service
manual (if it exists?) from Uniden? For a Radio Shack
it seems easy, just call the RS 800 order line.

Source record: 78349

I just finished testing a number of 4-400 and 4-250 that I had
collected over the years. I had paid anywhere from $2 to $15 for
them. Some were in used equipment such as homebrew amplifiers
and broadcast transmitters. Of the 17 that I tested only 2 were bad
and none had open filaments or gassey. Most gave me an output in
grounded grid operation of more than 650watts.
Of a lot of 5 that I got a month ago or so at an hamfest 4 were
in good shape. I only paid $2 each for those. I am pleased with
the results. I had marked each one as to its source and found that
the other bad one was from a ham that claimed it was practically
new.
There are good cheap tubes out there but you have to be
willing to take a chance at a cheap price and hope for the best.
This was an interesting experiment. Now for the 4-1000A's. I'll
have to finish up the new amplifier to test them.
I'd be interested in other hams experience with buying used tubes.

Hi John

Well, to answer your question as quick as possible. YES !
I am still on the air, first licensed in the early 1960's. Been
on the air ever since. I still build some gear, but not as much as
I used to. I have a shack full of Heath kit gear that helped teach me
soldering techniques, as well as trouble shooting. I enjoyed it so
much that I did make it a career. Just retired after 34 years as
a communications/radio technician. Worked on UHF and VHF
radios, handheld, mobile, base stations, repeaters etc. Also was
involved in data communications.

I won't begin to think that I could build a solid state SSB multiband
transceiver from scratch, but I do enjoy building regulated power supplies
and various shack accessories as well as various antenna's.

It was and still is a GREAT HOBBY, and the interest even put
food on the table and clothes on our backs. We, being my wife
and daughter.

I think we get out of a hobby, just exactly what we contribute
to it. I have had the pleasure of making friends all over the world
via HF on many different modes. I hope to continue on doing
so for at least another 30 years. I'm 55 now, so there is a good chance.
Not to mention all the new friends I have made by helping instruct
during the Ham Classes every year to help others become Hams.

As far as getting on the air, I do every day. Even if it's just for a quick
single contact. I also put some vintage gear on the air (made in 1943)
on November 11th. Of course it is on CW, and I issue a special colour
certificate and QSL card for anyone brave enough to have a 2-way contact
on 40 meters with me. I take great pleasue using that particular piece of
equipment (an old army WW II # 19 set) as it is also 55 years old.
We both still function, after all that time.

Well now, I can (and have) dropped a solid state radio 36 inches onto concrete. Picked it up and it was still working. I doubt most tube rigs could do the same. Solid state is very rugged. The old stuff is just heavy. (Maybe that's why they're called boat anchors.) :-)

>Mark Zenier mzenier@eskimo.com mzenier@netcom.com Washington State resident

It isn't an artifact of narrow filtering. Tune it with a SSB receiver and you'll hear the constant carrier as a constant amplitude hetrodyne note. If the carrier were varying with modulation, the hetrodyne note wouldn't be constant amplitude, but it is. The math predicts it, and the math is right.

Of course the carrier is varying *at the carrier rate*, as a sinewave. Duh! So if you use a filter narrower than the carrier rate, you see a constant amplitude. But it isn't varying at the modulation rate. And you *can* use a filter wider than the modulation rate and still observe the constant carrier as an unvarying hetrodyne note.

No difference, that I know of. Often an inductor is refered to as
a choke, as it is used to choke the AC and allow DC to flow through
a circuit.

>anyone enlighten me?

Really, there is no difference - they're different names for the same
component, also sometimes called a "coil". Which name is used
generally depends on the application.

The term "inductor" is actually relatively rarely used. It's usually
called a "choke" if it's used to remove alternating currents and noise
from the DC output of a power supply, or a "RF choke" if it's used to
keep RF signals from getting into a power or control circuit. "Coil"
or "Inductor" are more commonly used if it's used with a capacitor to
form a resonant circuit for selecting one frequency.

The same component can sometimes be used in any of these applications
depending on where it's connected in the circuit.

I have to disagree with some of the other posters.

An inductor is an electrical component. Other common components are capacitors and resistors. A choke is one of the applications for an inductor. A in inductor is called a choke when it's used to block, or choke, an AC signal while letting DC through. It's the opposite function of a blocking capacitor. Inductors have other applications besides chokes. For example, an inductor used as part of a resonant circuit isn't properly called a choke.

Hi Curt,

I've noticed similar things with some of the various nets and some operators in general. Personally, I never use the DX nets, I'd rather work them on my own. Anyone can work DX if the guy is waiting to hear you. If you can't, you'd better be thinking of a new antenna system. However, in the support of these nets, they do tend to lesson the QRM on the bands by keeping things a bit more orderly. I've learned to just ignore the attitudes of some of these people. I think that maybe a lot of them are bitter old men (not to say that all old men are bitter, hell, at 47 I guess I'm considered an old man HiHi) who long for the good old days of tubes, crystals, AM and resist change and things they don't personally like at all costs. For instance, this last weekend during the Cal QSO party, on every band I operated someone would show up and throw a carrier on top of my cq's. Since I have a modern radio with auto notch they weren't very successful in bothering me but they might have chased away a few trying to call me. I'm sure it wasn't directed at me personally since I've never made an enemy on the air (that I'm aware of). I'm sure it was just some dork who doesn't like contests since he's no good at operating that mode and figured that he'd single handly run everyone off the band. It didn't work. The contest continued without his approval. Probably someone who tells the same story to the same guys on the same frequency at the same time everyday and just didn't know what to do for and entire day without his 'sked'. Pretty sad person in my opinion! I don't understand it anyway, everyone knows when the contests are (if they read QST) and could easily make arrangements to move their skeds way 'up' the band where most contesters don't go anyway. Just arrogance and stubbornness in my humble opinion. A few contests ago I heard one old coot literally screaming at someone to move off 'his' frequency. The poor guy eventually did, only to have someone else move in a bit later and start calling cq contest so he gained nothing! When there's a contest, the bands are crowded, get over it guys!

Jim
Call withheld to avoid future carriers that might be directed at me personally

John OM,

I am happy to answer this question. YES!
After 43 years of being continously active on the air, I am still of the opinion that ham radio is the world's best HOBBY (and I have a few others to compare it with, too). I am on the air daily, CW mobile, and will be back on from my (new) home QTH as soon as I get my tower re-planted and the HF arrays back up on top. I'm a CW op mostly, but enjoy FSK too. I run homebrew XMTRs and RCVRS as well as older gear (in my experience, homebrewing has never been easier, cheaper, or more fun than it is today, contrary to what I hear from those who do not engage in it). Also, there are an awful lot of excellent ops out there, which (still) makes ragchewing such a pleasure. CU on the air.

73,
Don, W6JL

: If you could look (using an oscilloscope) at a single cycle of an AM modulated
: signal, and compare that with a single cycle of an unmodulated signal, you would
: find that the modulated cycle is slightly distorted and is not a perfect sine wave,
: like the unmodulated signal. Since it is distorted it contains more than a single
: frequency. These other frequencies are the sidebands.

Hmmmm.... OK, a little thought-experiment. Let's say I generated an AM
modulated signal such that the transmitted amplitude is constant for a
time, the changes to a different level during some transition time, then
is constant at the new level for a time, then in a second transition time
returns to the original amplitude. CW is an example of this, but so is
AM modulation by something like a trapezoidal wave. Now, it seems to me
that I can _define_ cycles in the constant amplitude regions to be
perfectly sinusoidal with no distortion whatsoever.

It seems to me that you must observe the signal for longer than a single
cycle to make any statements about sidebands. You may have to look at
the signal for rather a long time, in fact.

The other side of the coin: if I were to take the single cycle Bill
suggested, which is not exactly sinusoidal, and repeat that ad
infinitum, the result would be only harmonic distortion: the
carrier frequency and some set of integer multiples of that carrier
frequency, not at all what I would call AM. It is not the information
in a single cycle, but the value of the signal over a significant
period of time, that determines the overall frequency content, if you
elect to resolve the time domain signal into spectral components.

It most certainly *is* a mathematical consequence ("artifact," whatever)
of reception bandwidth. Jeez, will this thread never die?

Everybody, listen up. Try this, please, before posting any more
hand-waving answers to the thread. Give logic a chance. :-)

Apply a 1 Hz sine wave to the AM modulation input of a signal generator
with no DC blocking, and listen to the result on an SSB receiver with
the AGC off.

I will bet you hear the carrier being "modulated" then, loud and clear.

Nothing happens at 1 kHz that doesn't also happen at 1 Hz.

Curt,

That's the problem with most DX nets--only interested in a 59 and a QSL. I'm not knocking that, but if you want more, try calling CQ or look for DX stations other places on the band. Seems like the phone pile-ups have been rather unruly lately. Try CW--it's a bit (just a bit at times) more civilized.

As I'm sure Tom knows, but didn't mention, to get a true frequency-domain equivalent of any waveform that lasts for a finite length of time requires infinite bandwidth. And to get a true time-domain equivalent of any spectrum which isn't of infinite bandwidth requires an infinite time. Of course, we can never satisfy these requirements, but can usually (but not always) get close enough for practical use. The art and skill lie in figuring out just how wide a spectrum is necessary to get a good enough representation of a real time waveform, or how long a time waveform has to last to represent a real spectrum well enough -- and what's "good enough". It's easy to fall into the trap of thinking that what we see on a spectrum analyzer is a precisely accurate equivalent of a time waveform -- it's not, and sometimes, it's a poor representation indeed. Some of this is due to the limitations of the spectrum analyzer circuitry or the method used to acquire the spectrum, but some is due to the fundamental problem I mentioned. If you want to learn more about this topic, I recommend _Modern Spectrum Analyzer Measurements_ and _Modern Spectrum Analyzer Theory and Applications_ by Morris Engelson, published by Artech House.

If modulation is actually occurring during the "one cycle" interval then the distortion is there and sidebands of some kind are present. The exact nature of the sidebands may vary from one cycle to the next, but the basic principle involved is the same and my statement is correct.

A distorted RF sine wave contains sidebands, by virtue of its Fourier Transform. This distortion is the root cause and the fundamental explanation of the equation for the AM signal. This equation shows clearly that the shape of the carrier sine wave is being distorted while modulation is actually occurring during the interval of the sine wave.

I'm looking for any help offered to repair an old Belknap Shortwave Radio. Sources of info, scematics, replacement tubes, good advice. Its a 2 volt battery operated unit that looks to be early 1920's. Some of the preset stations on the dial are WGN Chicago, WHAS Louisville, WGY Schen'lady, etc. For starters, this will need a new tube (U5 is stamped on the base of the old broken one). All I've been able to learn is that Belknap Hardware & Mfg was in KY and went out of business in 1985. Thanks

Jim Knight

hello there i have two ssm europa transverter's one of 4m and one for 2m /
i am putting the 4m one onto 6m ,but what iam looking for is the wiring for
the power and control plugs on the rear of the unit /iam wanting to drive
them from my ts820s.
IF you have the wiring info that you could scane and e-mail to me that would
be great or if you have a manual that i could borrow and copy that would be
better i would take very good care if it and would return any cost's for
postage etc.

> >watts of drive
>
> And the linearity?

I don't see why it should be that much worse than a triode. However the life
of the valve would surely be compromised. What controls the standing bias?
Nothing! what was the grid dissipation - anyones' guess but probably rather more
than 2W. I expect the operating point would vary all over the place but then
again
the grid/cathode/screen "supply" voltage would be stiffly zero regardless of
screen/grid current, so it might be more like a grounded grid triode or a 4-250.

I expect they used a muffin fan for cooling, soldered directly to the base to
save
buying a base and changed the 4CX250 once a month.

Mike

There is some advantage to being strong and wide in contests - it discourages
operation
on nearby frequencies, but it ought to be properly penalised by the adjudicators,
which
I have found not to be the case.

What you have actually demonstrated is that you *can* add these three signals together to produce a single signal whose amplitude sometimes goes to zero. But you could equally well produce the same single signal by amplitude modulating a single-frequency carrier. Once you have that single signal, you can't tell how it was created. Mathematically, and physically, these are two different ways of creating the same signal.

When you go to analyze the signal, you can analyze it as three separate sinusoids - carrier plus sidebands. Or, you can analyze it as a single frequency carrier amplitude modulated by a particular signal. Since the same signal can be *created* by either of two methods, it can be *analyzed* in either way.

And just as either method is an equally valid way of producing the single waveform, either method of analysis is equally valid. So it is perfectly reasonable to *create* the waveform by modulating a carrier, but *analyze* it as three sinusoids at different frequencies (which is

what usually happens). It's just as valid to create the waveform
by mixing sinusoids and analyze it as modulated single-frequency carrier.

Indeed, you can mathematically transform back and forth between the two
representations without bothering to physically create and analyze the
waveform. The Fourier transform provides the tools to do this.

So it's the *same* waveform however you create it, and it's the *same*
waveform however you analyze it. Both analyses are equally valid
at the same time. They are just equivalent descriptions of the
same process. Sometimes one provides more insight into a particular
problem than the other, but both are valid.

Why is this so controversial?

Dave

: > . . .

: As I'm sure Tom knows, but didn't mention, to get a true
: frequency-domain equivalent of any waveform that lasts for a finite
: length of time requires infinite bandwidth. And to get a true
: time-domain equivalent of any spectrum which isn't of infinite
: bandwidth requires an infinite time. Of course, we can never satisfy
: these requirements, but can usually (but not always) get close enough
: for practical use. The art and skill lie in figuring out just how wide
: a spectrum is necessary to get a good enough representation of a real
: time waveform, or how long a time waveform has to last to represent a
: real spectrum well enough -- and what's "good enough". It's easy to
: fall into the trap of thinking that what we see on a spectrum analyzer
: is a precisely accurate equivalent of a time waveform -- it's not, and
: sometimes, it's a poor representation indeed. Some of this is due to
: the limitations of the spectrum analyzer circuitry or the method used
: to acquire the spectrum, but some is due to the fundamental problem I
: mentioned. If you want to learn more about this topic, I recommend
: _Modern Spectrum Analyzer Measurements_ and _Modern Spectrum Analyzer
: Theory and Applications_ by Morris Engelson, published by Artech
: House.

Thanks for the comments, Roy. Yes, in fact if you use an FFT-based
spectrum analyzer, you'll commonly have a choice of "windowing"
functions which let you modify the input signal in the time domain
so that it behaves in ways that are more easily analyzed by you,
the spectrum-analyzer-user. For example, if you have a waveform
which is exactly periodic in the time block captured by the
analyzer, you may decide to use no windowing at all, and have
better resolution as a result; but if you have an arbitrary signal,
selecting some windowing can let you more accurately estimate the
amplitude of certain spectral components.

The shape of a single cycle of a signal that changes from cycle to cycle
would never give you anywhere near the amount of information you would
like to have to analyze the signal. It is the variation over lots of
cycles which determines the spectrum, NOT the shape of any one
individual cycle. On the other hand, for a modulated carrier, you can
get all the information you need by sampling at a rate far less than

once per cycle of the carrier frequency, assuming that you either already know the carrier frequency or don't care about it. An AM signal, for example, could be sampled at a few times the rate of the highest modulating frequency to get all the info you need about the sidebands.

In summary, you must sample for a long enough TIME to let you resolve one spectral component from an adjacent component. And you must sample FAST ENOUGH during that time to cover the whole _range_ of frequencies of interest. Sampling infinitely fast (e.g., continuous time acquisition) does NOT help you resolve one spectral component from an adjacent one; that only comes from sampling for a long enough time. One cycle of the carrier just is NOT going to do it. Sampling for a second gives me a chance to resolve components one Hertz apart. Sampling for one microsecond gives me a chance to resolve components 1MHz apart.

Please, Please don't do it. The 4CX... are designed for use as tetrodes.

The extra complexity of the screen supply is minor in comparison to the metalwork and HT supply. Take some pride in building a clean LINEAR amplifier.

There is a lot of excellent information about how to design/build cleanr LINEAR amplifiers in 'THE VHF/UHF DX BOOK' pblished by the RSGB (ISBN 0 9520468 0 6).

Actually, I don't see any other way to generate the composite waveform
shown without having the carrier and both sidebands present.

It appears when you have that composite waveform, it immediately tells
you there are three signals present - no more and no less.

Therefore, the carrier is not affected by the modulation process, and is
present at all times.

[...]

> Why is this so controversial?
>

I think we are confusing the results when we see all three signals add up
to zero, and assume the carrier must have gone to zero.

Best Regards,

Mike

3267. How feed/tune loop above pickup truck?

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-10-06 00:00:00 UTC
From: mcalhoun@ksu.edu
Message-ID: <6vdvsa$eqm@cbs.ksu.ksu.edu>
Source record: 78306

Lotsa background first; questions are 'way down near the bottom.

I've been experimenting with antennas on my 1981 F-100 pick-up truck with an aluminum "topper" about six inches higher than the cab. Rig is an old 5-band CW/SSB Ten Tec Triton IV (aka Model 540) running about 100 watts. Vehicle has two batteries, one for the radios and one for the vehicle: they are charged in parallel via a continuous-duty solonoid, and an out-of-sight under-the-hood switch permits starting from either (potential anti-theft gimmick? switch has a center-off position; I can start vehicle, open hood, turn switch off, drive somewhere, park, turn off vehicle--and it won't start again!) In-cab pilot lamps show which battery is being used for starting, and a switch-selectable DVM monitors battery voltage (although the DVM goes "haywire" when transmitting on HF!)

First I installed two single-whip mounts on the side of the truck body; both on left side; one is about a foot behind the cab, the other is about a foot forward of the very rear. When a whip is mounted, each must "contend" with 2.5 to 3 feet of "topper" only a few inches away from the whip. I bought a set of five single-band whips and quick-disconnects from PRO-AM. (I already owned 40- and 20-meter PRO-AM whips--called "old" below--and liked them very much; they only cost about $20 each new!)

To test/tune the antennas individually and sans the effect of a large metal vehicle, I cobbled a test mount using some plexiglas holding a quick-disconnect about two inches above a heavy foot-square piece of eighth-inch iron; four radials (about 33' each) and a 4' ground rod attached to the coax shield, and the set-up was in the middle of a large field with very wet soil (we've had quite a bit of rain lately), with about 90 feet of coax running from where I sat with a battery-powered MFJ antenna SWR meter.

By adjusting the "stinger" on each whip, I set each antenna to a convenient center frequency and recorded the VSWR and antenna resistance. For those who want the whole details, here are the results I recorded:

```
* HIGH & LOW frequencies are at VSWR = 2:1 points
---- FREQUENCIES ---- VSWR EST. STINGER
ANTENNA HIGH* CENTER LOW* :1 OHMS LENGTH
-----------------------------------------------------
75 3.93 3.905 3.88 1.3 43 39 3/ 8"
-----------------------------------------------------
old 40 7.31 7.247 7.20 1.6 40 40 3/16"
new 40 7.31 7.252 7.20 1.55 40 40 3/16"
-----------------------------------------------------
old 20 14.62 14.238 13.89 1.3 44 40 9/16"
```

new 20 14.67 14.289 13.89 1.2 45 39 11/16"
---
15 22.41 21.352 19.87 1.05 51 42 7/16"
21.473 1.2 45
---
10 31.03 28.543 26.23 1.1- 55 34 15/16"

(I say "ESTimated OHMS 'cause the MFJ meter isn't very large.)

For both "old" and "new" 40-meter antennas, the SWR seemed a bit high, and I suspect there just weren't enough radials; as a quickie test, I halved the radial lengths and the SWR changed to 1.7:1. To me, this kinda confirms my suspicion, but since I was just "playing" before installing them on my vehicle, I didn't pursue this any further.

For the 15-meter antenna, just for fun, I disconnected the radials altogether; just the 4' ground rod was present. (This happened to be the last test I did.)

Without changing the stinger lengths, the antennas gave the followng readings from the MFJ when they were ONE-BY-ONE mounted on either the "rear" or "front" mount (as described above) on the truck:

FREQUENCIES VSWR EST.
ANTENNA CENTER :1 OHMS
---
75 REAR 3.815 2.4 45
FRONT 3.805 2.3 40
---
old 40 REAR 7.213 3.5 90
FRONT 7.21 3.0 65
---
new 40 REAR 7.245 3.1 115
FRONT 7.21 3.0 65
---
new 20 REAR 14.62 1.7+ 37
FRONT 14.58 3.+ 60
---
old 20 REAR 14.52 1.85 40
FRONT 15.55 3.++ 60
---
15 REAR 21.73 1.8 47
FRONT 22.00 2.2 33
* REAR 21.325 I didn't record SWR & ohms
---
10 REAR 31.87 1.65 39
FRONT 29.13 3.++ 65
* REAR 29.00 3.0 forgot ohms
* FRONT 28.500 3.0 forgot ohms

For most of the whips, the center frequencies didn't change too much, but I re-adjusted the "stinger" lengths on the 10- and 15-meter whips (marked by asterisks above). I suppose the nearby metal "topper" is affecting both frequency and SWR; and changing the "stinger" lengths didn't really help the SWR.

Personally, the SWR's were ROTTEN! To make my no-tune radio happy I have to use a tuner (homebrew, of course: about 8 inches of a wide-spaced 2" B&W coil with one capacitor and two alligator clips in a Tee configuration.) Works fine, but not really handy for QSY'ing while driving. When I get all done, I'll substitute a band-switched tuner.

Overall results are OK, but no cigars (sorry!-) for stellar performance--perhaps what could be expected of mobile work?

Since I have two pairs of same-band whips, I used one set to cobble a horizontal (runing fore and aft) 40-meter DIPOLE about 2.5 feet above the top of the truck cab and "topper". Looks wierd, I still have to use the tuner, and the vehicle is now just a fraction under 9 feet high (just fits in my garage), but it gets out like blue blazes!!!!
(I was worried about how the forward-pointing whip would take 65 MPH winds, but I shouldn't have; the tip barely moves in a small-radius [maybe 6-inch diameter] circle! I can see it by leaning forward and looking up, or, if the sun is mostly overhead, it casts a shadow on the hood of the truck.)

```
---- FREQUENCIES ---- VSWR EST.
ANTENNA HIGH* CENTER LOW* :1 OHMS
-------------------------------------------------
NVIS DIPOLE 7.183 7.155 7.134 1.55 47
```

It may just be the advantages of a horizontal dipole versus a quarter-wave vertical, but I also suspect there may be some NVIS (Near Vertical Incident Skywave) effect. I'm going to try the 20-meter pair next, which should differentiate between the dipole vs. vertical since 20-meter signals probably won't produce much in the way of skywaves.

QUESTION COMING: Then I added four wooden (broomstick) corner posts and installed a "square" single-turn LOOP which is also about 2.5 feet above the "topper". (Truck now looks REALLY wierd going down the road!) Width of "square" is 67 inches and length is 98 inches, for a total "circum-ference" of about 27.5 feet. The loop is broken in the middle of the width right above the cab/topper boundary (where the "mast" for the 40-m dipole is located), although I could corner feed it with no difficulty.

I need to borrow the MFJ meter again; until then, I can't report any measurements.

For a quick-and-dirty test, I connected the two ends of the loop to my tuner with about 9 feet of coax (one end of loop to shield, one to center conductor); the tuner WILL "match" it (it'll match a wet noodle!) such that the SWR is about 1:1, but I can NOT hear worth a hoot (and no one responds to calls!) Even a vertical on the side of the truck is better.

QUESTIONS: HOW SHOULD SUCH A SMALL LOOP BE FED?
AND WHERE?
HOW MANY TURNS ***SHOULD*** IT HAVE?

I can add tuning coil(s?) at the feedpoint to "lengthen" the loop.

I can add more turns (before mounting the broomsticks, I drilled ten holes at one-inch spacing in case I need multiple turns); what spacing should I use?

Although it'll look even worse, if I can find longer broomsticks, I can move the loop forward another five feet or so, making the total "circumference" about 37 feet; will that help?

FWIW, I hope to cover (i.e., be able to tune) 80 and 40 meters for NVIS purposes. I suppose I can mount a box with tuning components and relays 'way up there, but maybe I'd better go back to the dipoles?

Good comments and/or suggestions will be appreciated. If I learn anything significant, I'll post a summary.

I truly miss not being able to operate like I did when I was first licensed. The enthusiam has not waned, but the QTH has. Since moving to Virginia, I have only been able to operate during FD. I love it, but it isn't ragchewing, and that is a great part of the hobby for me. I miss the all nighters working into Asia and Europe. I miss sharing historical events with people from other walks of life. I hope to be able to someday move into a QTH that I can at least string a wire up.

Thanks guys for the info. I have built a few amps using these tubes and found them to be a joy to put on the air. I had never tried one in the GG before and when I saw the diagram thought it might be interesting to try if I could find some more info on it. Every thing I knew about it said this was a bad idea and not worth the effort or risk of wiping out a moderately expensive tube but it did appear that someone had done it before. I think I will stick with the grounded cathode amps for these tubes.

Whenever enegry is added or subtracted via the modulator at an instantaeous point on the carrier the slope of the carrier is changed thefore this energy is no longer at the carrier frequency but at the sideband frequency. Hence no energy is added or removed from the carrier. All power in the sidebands is that supplied via the modulator.

I respectfully disagree! Sorry I haven't until now.
The original configuration you described, if I recall correctly, was:
driven thru cathode.
cathode and grid tied together
no screen supply; screen grounded
That's "supercathode" drive. Bill Orr wrote an article about it in
QST back in the '60s (I believe it was called "Semi and Super Cathode
Driven Tetrodes"). I can supply the precise reference upon request.
You can run a 4CX250B type tube just like that, with about 75W drive,
to 375W output without exceeding the ratings.
In broad terms, it works like this:
Grid voltage is always zero, since "grid voltage" actually is
grid-to-cathode voltage, and they're tied together.
With no signal, very little plate current flows because screen voltage
is zero.
When the cathode swings negative due to drive voltage, the screen
voltage (actually screen-to-cathode voltage) swings an equal
amount...cathode drive voltage=100V means screen voltage=100V. So
plate current flows.
It's kinda like a screen-modulated AM xmtr.
And the fun part is the linearity actually IMPROVES for this
connection...Eimac measured 3rd and 5th IMD both better than -40dBc as
published in this article.
So it's a viable design. The disadvantages are that very few tetrodes
can be connected this way without either (1) exceeding the rated
screen dissipation or (2) requiring ridiculously large amounts of
drive. Consider this example, the power gain is only around 6dB (75W
to 375W), not usually consider too whippy in power amp design.

3275. Re: 4CX250 Grounded Grid Amp

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-10-06 00:00:00 UTC
From: Al Dolgosh <al.dolgosh@hamradio.org>
Message-ID: <361ABBB1.4297AD2C@hamradio.org>
Source record: 78314

The main reasons for running grounded grid are:

1.) Inherent amplifier stability

2.) Drive power (100 w) compatibility without attenuation

I solved these problems a number of years ago, when I built a bandswitching 80 - 10 meter amp with four 4CX250Bs in parallel. As long as you have to apply the screen and control grid voltages, why not grid-drive the amp? You can build a passive-grid circuit by simply using a resistor from a Heathkit Cantenna (or similar 50 ohm non-inductive resistor) from the input connector to ground. The RF voltage developed across this resistor by 100 watts is almost exactly what is required by the 4CX250B. I then coupled the RF to the grids (in parallel) with a .01 mfd transmitting mica capacitor.

This results in a very low impedance grid circuit with high stability.

Because of the multiple tubes-in-parallel configuration, I used a few low-resistance (100 ohms, I think) series resistors to each screen grid and similar balancing of the control grids - all in parallel.

The stability was excellent, I didn't need to attenuate the 100 watt exciter and didn't have to worry about building the bandswitching grid circuit! The "Cantenna" resistor was mounted below chassis in the air stream so everything was cool!

Hello--

I'm offering the following NOS items for sale-- e-mail me for additional

details on any items or to reserve any item:

*****

Western Electric tubular capacitors: 0.1 uf +/- 20 per cent, 600 volt;

glass-sealed metal-cased w/case connected to one lead; 2.5-inch axial

leads; case is insulated w/clear plastic sleeve. Date code 7737

$3.20 each (98 pcs. available)

*****

ITW Quencharc (tm) arc suppressor/snubber network-- 0.5 uf/600VDC
cap in series w/22 ohm resistor. Molded in epoxy; radial leads on 1.25
inch centers. Similar to Mallory Q/QRL series. $.50 ea (58 pcs. avail.)
*****

High-voltage Philips metalized plastic capacitor-- 0.015 uf/2KVDC.
Molded in blue epoxy; radial leads on 1.0 inch centers. $.50 each (120
pcs. avail.)
*****

Six-lug terminal strips (AKA tie-point strips)-- identical to Keystone

p/n 825 and similar to Cinch p/n 54B (but with six instead of the 54B's

four lugs). No ground lug.

$8.00 per 100; $15.00 per 200; $45.00 per 1,000
*****

Multi-output toroidal xfmr. ass'y.(ideal for heating arrays of

inexpensive sweep tubes); selectable primary: 100, 120, 240 VAC

Measured Output Voltages (from four isolated wdgs.):

Output 1: 17 VAC, 4A nominal

Output 2: 22 VAC, 4A nominal

Output 3: 60 VAC, 1A nominal

Output 4: 80 VAC, 1A nominal

Connect wdgs. in series for 39; 77; 82; 97; 99; 102; 119; 140; or 179

VAC.

Price-- $24.00 each (plus postage for 10 lb. to your location) 24 pcs.

avail.

*****

833A Xmtg. triode (ex-distributor NOS GE, 1964 d/c), orig. box. One only. $90.00

*****

816-JR Mercury-vapor rectifiers; NOS but unboxed. Test as new; 4 pcs. avail. $14.00 ea; $44.00 for the set.
*****

46 "Dual Grid" triode: tie Gs to plate and run single-ended class A for 1 watt, or tie Gs to control grid and run a p-p pair in class B for 20 watts. Filament: 2.5V@1.75A; plate rated to 400 V. Base connections: 5C These are boxed NOS: 5 pcs. RCA; 3 pcs. Tung-Sol; 1 pc. "Tip-Top" brand; 1 pc. misboxed Philco. Boxes grade 6/10 (dusty; torn flaps). Filaments get a continuity check before shipment; getters all appear shiny. $15 each; (the misboxed Philco tube goes free to whoever buys the largest qty.)
****

I accept payment via personal or cashier's check or money order drawn in

U.S. dollars and made payable to "Brad Thompson".

For U.S. shipments, add postage of $3.00 for priority-mail shipment of small parts (capacitors, terminal strips up to 200 pcs). For 1,000 terminal strips, add $10.00 postage. Inquire for tube and transformer shipping charges.

Overseas purchasers: tell me your location, and I'll calculate

appropriate postage.

These components are subject to prior sale and are supplied as-is, as

new-old-stock (NOS) merchandise, with all responsibility for safe and

successful application residing solely with the purchaser. If you find these components unsatisfactory upon your inspection, you can return your purchase in as-received condition for a fund within ten days.

Brad Thompson, AA1IP

P.O. Box 307, 202 Whitaker Rd.

Meriden, NH 03770-0307

yes, un solder one leg of diode d-29 and lift it off the board to break contact. this mod is very helpful when using the dial-tuning knob but..... when you use the other functions such as memory presets it sounds like a car wreck. these sounds must be the reason for the mute in the first place.

Don,

Thanks for your reply.

I didn't want to directly advertise here since newsgroups are intended
for people exchanging information and ideas. I like to play by the
rules :)

To answer your questions... all of the details, including prices are
listed on the web page at www.pcbmilling.com

Board sizes range from 3.5"x5" to 7"x10" and there are no per hole
charges.

If you have any more questions please email me at
feedback@pcbmilling.com and I'll be glad to go into more detail.

Thanks and 73s

Mark

>

Audio + a "DC offset" constant mixed (multiplied) with an RF carrier
will give AM.

Forget the offset and you get DSB-SC, get the offset wrong and you
either waste carrier power or get distortion on peaks.

Put the audio through a delay so that a smart transmitter can look
ahead a little to see what's coming, and so control the offset value and
you have a model for the variable carrier power systems.

AGC loops work fairly well, but for VCOs that have to change frequency quickly, watch out for problems with the response of the amplitude control loop stimulated by sweeping or hopping.

Another approach is to build an oscillator amplitude control mechanism around a limiting amplifier. This gives a *very* broadband removal of amplitude variations. Because of AM to PM conversion effects in the oscilllator and subsequent stages, this gives a useful net benefit in phase noise.

3287. Tuning mod for DX-390????

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-10-06 00:00:00 UTC
From: wmeara@erols.com

There is a very easy mod for these Radio Shack /Sangean SW PLL radios
(the ones with the BFO) that disable the "mute while tuning" feature.
Anyone remember what it is?

Thanks, 73 Bill N2CQR

Well, I patronized them numerous times before they moved to the new, smaller (horrible) quarters where you couldn't see or do anything. No wonder people would not go there. It was terribly small and they had almost nothing you could look at.

I was sorry to see it go, but are you sure that you are laying blame on the right source?

MRC was a great shop back when they allowed the meetings there, the library was great, and the store was easier to shop in.

The free parts exchange/magazine exchange was a great heolp to me, and the TUBE BANK was an awesome idea!

If only SOMEONE in the DC area would maintain a TUBE BANK now, I would certainly contribute to it and use it!

I was just sorry they had to move it from behind the Toyota dealer. After they opened the new place I only went in once. That was enought o put me off!

I will forward your comments to the DC BOATANCHORS mailing list and see if others have comments.

Maybe that's because you don't understand the reason for it, Mike.
The driving factor for many HF operators is the DXCC award. Last
nite, on 15 meter CW, I worked 423 stations in Europe in about 3
hours. A few probably called for pileup practice, but most of them
just wanted a contact for a 'new one', another QSL card. I probably
worked 95% of the stations I could hear, but I didn't work everybody.

I wouldn't have had many, if any, meaningful conversations if I had
spent a half hour per contact, instead of 20 seconds. And the end
result is all the same. Nobody called me, they called my QSL card...

They get a new one, I get warmed up for the next CW contest.
We are all happy. Nothing cold about that.....

73, Jim KH2D

Try that with a 100 percent modulation by a 5 Hz squarewave, (bandwidth
limited, if you want). (That's the situation similar to what the original
poster was using as an example). The carrier does go away in a time scale
shorter than that determined by your instrument's frequency resolution.
You're not going to "see" anything in the gaps, unless you have your ultra
narrow filter (analog or IIR) that's ringing or a DFT or FIR filter that
shows things blurred over the sample period of the system.

Ted,

I'd be interested to hear more about your experiences with PCB manufacturing.

At this time I do not offer thru-hole plating. As a small business just starting out I need to pull myself up by my bootstraps and first show some revenue, paydown the loan, etc. I desperately want to add a thru-hole plating capability ASAP! I'm going to look into a few options in the meantime, though. Not having this capability is one reason I'm offering to do boards for much less than full-up PC houses.

There's a really good description/discussion of thru-hole plating equipment and techniques at www.thinktink.com (think and tinker, ltd) along with recommendations on how to make homebrew thru-hole plating tanks. Since I'm looking at this from a business standpoint, though, I would prefer to invest in "real" equipment that is supported by a manufacturer.

For now I'm recommending that users either solder "Z" wires between both sides of a double-sided board or use eyelets. I know of a few sources of eyelets but I still need to come up with a coordinated list of suppliers that customers can use. I may consider selling eyelets later along with the boards.

Thanks and 73s.

Mark

I have been using LPKF for more than 10 years and it is a GREAT way of making prototype and 1 off pcb's. The current LPKF91s is a nice machine and as said in previous messages the only thing missing is indeed thru-plating. LPKF have a system using special chemicals and a vaccuum dispenser, but it seems a bit cumbersome. LPKF even offers systems for multi-layer...

But based on my experience, if I need a thru-plated pcb or a multilayer I usually go for the "real thing" and stick to the LPKF when need that prototype board.

Good Luck with your buisness

Cheers

3308. Making PCB.....

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-10-07 00:00:00 UTC
From: spam@nospam.com
Message-ID: <361b178d.2150352@news.lin.foa.se>
Source record: 78329

Hi gang!
most of us knows how to etch a pcb and the result is usually OK. If extra finish is needed one can chemically plate the board with tin or silver. But I have yet to see anything on solder stop masks !?!

As I understand this must be a photographic process as the photo-resist. But what is used and where do I get the stuff, in smaller quntities (less than a gallon). Using a solder stop coating it nicely covers the minor rough spots on the board and ease up the soldering work.

Please, anyone with experience in this process share your wisedome!!!

Cheers

Thanks Jim. Never used the memory so I never noticed. I recall an
easier way of doing this. It involved cutting one of the wires in one
of the ribbon cables. thanks, 73 Bill N2CQR

3310. Re: testing used 4-400's etc.

Newsgroup: rec.radio.amateur.homebrew

Before 8 months i built amp with used 4-250 (phillips eq. qb3.5/750).I was gifted with pair of used tubes and pair of brand new.There are still used tubes in amplifier.After about 3000 QSO's (ARI contest,CQWW WPX CW,some local contests)this amp delivers 1.3 kw out from 80 to 20 m,900w on 15m and 600 w on 10m (bad placed PI network).
HV is 3500V (loaded),GG amp,100w enough for drive.
I'm very satisfied with tubes.Its hard to find cheap ceramic tubes suitable for GG (triodes).Very hard.

3311. Computer Power Supply and Hand Held

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-10-07 00:00:00 UTC
From: "@Home News" <gdulmage@home.com>
Message-ID: <9WIS1.10075$Mq1.4071940@news.rdc1.on.wave.home.com>
Source record: 78332

I have a computer power supply that has an output of 12 volts at app. 2.5 amps. Can I use this to power my ADI AT-201 2 meter handheld? The handheld requiers a voltage between 5 and 16 volts DC.

If it can be used:
- does it need to be modified and how?
- Can the voltage be increased to 13.8 volts DC and still give me at least 1 Amp?

>>
>>Jim KD4RQE

The gain figure is the main thing that has turned me off to this amp, unfortunately I left it out of my post. I was hoping for an amp with at least 10db of gain which is about par for GG. Basically I was looking for an easy way to build an amp for 15 through 6 meters without the screen and bias supply normally associated with these tubes.

Thanks for your reply
Jim

The switching regulator needs a load on the 5 VDC line in order to work.
You can hang a fairly hefty power resistor on this line and it will probably
work Ok.

>- Can the voltage be increased to 13.8 volts DC and still give me at least 1

Probably not easily. Be content with 12 VDC.

3317. W-E caps sold; parts FS (long)

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-10-07 00:00:00 UTC
From: Brad Thompson <Brad_Thompson@pop.valley.net>
Message-ID: <361B87CD.41FC@pop.valley.net>
Source record: 78338

Hello--

I'm offering the following NOS items for sale-- e-mail me for additional

details on any items or to reserve any item:

*****

Western Electric tubular capacitors: SOLD

*****

ITW Quencharc (tm) arc suppressor/snubber network-- 0.5 uf/600VDC
cap in series w/22 ohm resistor. Molded in epoxy; radial leads on 1.25
inch centers. Similar to Mallory Q/QRL series. $.50 ea (58 pcs. avail.)
*****

High-voltage Philips metalized plastic capacitor-- 0.015 uf/2KVDC.
Molded in blue epoxy; radial leads on 1.0 inch centers. $.50 each (120
pcs. avail.)
*****

Six-lug terminal strips (AKA tie-point strips)-- identical to Keystone

p/n 825 and similar to Cinch p/n 54B (but with six instead of the 54B's

four lugs). No ground lug.

$8.00 per 100; $15.00 per 200; $45.00 per 1,000
*****

Multi-output toroidal xfmr. ass'y.(ideal for heating arrays of

inexpensive sweep tubes); selectable primary: 100, 120, 240 VAC

Measured Output Voltages (from four isolated wdgs.):

Output 1: 17 VAC, 4A nominal

Output 2: 22 VAC, 4A nominal

Output 3: 60 VAC, 1A nominal

Output 4: 80 VAC, 1A nominal

Connect wdgs. in series for 39; 77; 82; 97; 99; 102; 119; 140; or 179

VAC.

Price-- $24.00 each (plus postage for 10 lb. to your location) 24 pcs.

avail.

*****

833A Xmtg. triode (ex-distributor NOS GE, 1964 d/c), orig. box. One only; be loud; be very, very loud. $90.00

*****

816-JR Mercury-vapor rectifiers; NOS but unboxed. Test as new; 4 pcs. avail. $14.00 ea; $44.00 for the set.
*****

46 "Dual Grid" triode: tie Gs to plate and run single-ended class A for 1 watt, or tie Gs to control grid and run a p-p pair in class B for 20 watts. Filament: 2.5V@1.75A; plate rated to 400 V. Base connections: 5C These are boxed NOS: 1 pc. RCA; 1 pc. Tung-Sol; 1 pc. "Tip-Top" brand; 1 pc. misboxed Philco. Boxes grade 6/10 (dusty; torn flaps). Filaments get a continuity check before shipment; getters all appear shiny. $15 each; (the misboxed Philco tube goes free to buyer of all three tubes).
****

I accept payment via personal or cashier's check or money order drawn in

U.S. dollars and made payable to "Brad Thompson".

For U.S. shipments, add postage of $3.00 for priority-mail shipment of small parts (capacitors, terminal strips up to 200 pcs). For 1,000 terminal strips, add $10.00 postage. Inquire for tube and transformer shipping charges.

Overseas purchasers: tell me your location, and I'll calculate

appropriate postage.

These components are subject to prior sale and are supplied as-is, as

new-old-stock (NOS) merchandise, with all responsibility for safe and

successful application residing solely with the purchaser. If you find these components unsatisfactory upon your inspection, you can return your purchase in as-received condition for a fund within ten days.

Brad Thompson, AA1IP

P.O. Box 307, 202 Whitaker Rd.

Meriden, NH 03770-0307

(603) 469-3351 (call between 9:00 AM-9:00 PM Eastern time, please)

You can't do it. There are no cavities inside to filter out the 600kHz
offset. The filters are barely narrow enough to keep police/fire/pagers
out of the ham bands as it is. I think that somewhere in the manual it
states that the VHF/VHF and UHF/UHF x-band is also disabled in the firmware.

Thanks for the reply.

The LPKF equipment is really great stuff, no doubt about it. I agree though about the Auto-Contac system they sell which uses conductive epoxy and a vacuum system to suck out the unused epoxy. I've never used it but it really looks like a real pain in the rear!

I agree in the sense that, sometimes, you just need to move up to services that use plated-thru holes. Unfortunately, this costs more than what I'm charging for boards. I work around the plated-thru hole problem by soldering "Z" wires between layers or using eyelets in areas where thru-holes are needed. Frequently I design around the unplated hole limitation by placing an extra set of small pads just past the edge of a "trapped" part and then use Z wires to join top and bottom tracks.

I'm really trying to cater to the "inbetween" market; people that use either resist pens, heat transfer sheets, or photographic methods to make boards for their hobby work (they don't have plated-thru holes either!) but don't want to step up in price to a "full up" board run. I'm offering precision drilling, contour and interior routing, and professional grade tolerances for those doing RF or surface mount work, something hobbyists just can't do with standard hand tools.

When I get things up and running I do want to add a plated-thru hole capability as soon as possible. This would really open up a whole new level of service.

How ironic; I just replied to your other message about the LPKF machine.. Since you know about the 91s you may want to investiage this.

Check out the LPKF site (www.lpkf.de). They have a film that can be milled on their machines for doing soldermask work. I've never worked with it but it might be worth checking out.

Source record: 78253

Hi Mark
well I guess I got fired up by commenting on your previous thread....

Had a look at LPKF german homepage but could not fing anything that mentions soldering masks. They use a laser to cut out metal masks for very fine geometry pcbs. Using a milling machine and mill away a soldermask sounds a bit risky to me! Controlling the depth of the tool would be difficult. Thicknesss of the copper is 15-30 thousands of a mm. Wear and tear of the mill bit would make it very difficult not to cut into the copper.

I guess this would mean going for a photographic process. Sholud be something like putting on etching resist. But somehow I am unable to find the stuff in any catalogue!

If you want to change tips and tricks on the LPKF I would be glad, please use larsm@lin.foa.se. We have been using our 91S since 1995 and before that we used simpler milling machine with no computer interface. But this machine is unbeatable for really *fast* protos as I can do the layout with pen and paper and then with no computer or CAD, mill the pcb. we are talking seconds here not hours. But of course it has its limitations but then againg we do have the 91S

Sorry for posting under alias but I am so utterly fed up with the spamming, I rather take the inconveniance using a phoney email adress.

Cheers

Came by a bunch of motorola stuff several months ago. In that was a power supply. The number on the back was TPN 1062 A . Not sure if that number will help, but if you have any info on it I would appreciate it.

Johnny Carter

3327. Light Table needed

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-10-08 00:00:00 UTC

Need a small low cost light box for tracing pcboard patterns, with
a strong top that won't score or scratch,
and viewing area of about 4x5 inches. What do you folks use that costs
less than $50 such as StainGlass cutting tables or kiddie table?
Any hints for sources?
Thanks, 73, W6MIK

Source record: 78258

1. the first 8 bits of N are DUMMY. U dont need them, 16 bits should be
good enough, but havent been tried. BITS are MSB first.

2. N = REF_FREQ / StepSIZE for VHF (no harmonics)
10400 / 5 is 2080 or 0x820

N = REF_FREQ / (StepSize / 3) for UHF (3rd harmonic)
10400 / (12.5 / 3) is 1496 or 0x9c0

N = REF_FREQ / (STepSize / 6) for 800 (probably)

3. when U do build an interface , please use a buffer like 74LS244 for
PLL2002 protection.

4. Did you figure out the riddle as to why writing <that long string>
tunes the scanner to 162550 ???

I have one made from a discarded sign. I was a box with a light inside that shown through a colored plastic sign. I remomed the sign and replaced it with a piece of frosted acrylic. You could always build a wooden box with a small lamp inside. Shouldn't cost more than $20.00.

3331. Any opinions on "T-Kit Model 1209 Transverter"

Newsgroup: rec.radio.amateur.homebrew

Does anybody have put together "T-Kit Model 1209 Transverter"?
How difficult is it to build (put together) the transverter?
How does it perform? Any opinions will be greatly appreciated.
Thanks.

Dave,

I've got one that used to be used as a slide sorter table that measures about 18" on a side. It has a frosted milk/white face. I haven't used it for years. If you want it it's yours for the cost of shipping. I'll have to dig it out and weigh it if you're interested. You could check local photo shops for something similar.

To all of you who e-maild, thanks for the info. I have ordered the LDG unit, and I'm happy to not have to re-invent the wheel. It is based on the micro I probably would've used anyhow, the 68HC11.

I just feel a bit foolish for not finding it in QST. I dug out the JAn 96 copy and there it was!

Thanks again to all!

Mark Zenier (mzenier@netcom.com) wrote:
: Try that with a 100 percent modulation by a 5 Hz squarewave, (bandwidth
: limited, if you want). (That's the situation similar to what the original
: poster was using as an example). The carrier does go away in a time scale
: shorter than that determined by your instrument's frequency resolution.
: You're not going to "see" anything in the gaps, unless you have your ultra
: narrow filter (analog or IIR) that's ringing or a DFT or FIR filter that
: shows things blurred over the sample period of the system.

Many people have posted that the _carrier_ varies over time. I'm quite
willing to let them think in those terms. It matters not to me. But
my view, which serves me well, is that the _composite_signal_ varies
in amplitude over time. To me, no matter what the modulation, I can
decompose the composite signal into components representing what I
call a "carrier" and what I call "sidebands." The time-domain view
of the signal is useful sometimes, and the frequency-domain view is
useful sometimes. To me, it's more enriching to be able to see both
views. It gives me a more complete picture, something I can better
internalize, than just a single view. It's as if you could only
see a side view of people, and could never see them from in front;
that would be a less rich and less interesting world to me.

YAH ! !
$10 tops.
The only ones on the Green country hamfest were $75 each and the useful parts
seem to include being able to make an antenna tuner from them, that does good
stuff.

I haven't made a tuner in a long time, but the price cop is guilty of

A few years ago, I saw an add in a ham radio magazine about a controller for the Ramsey FT transceiver kits. This controller gave full tuning of the entire band, 20 plus memory channels, encode and decode, etc.. I believe the name of the company that manufactures it is something like MicroTek.

Can anyone confirm the name of the company and supply a phone number or address?

Thanks

Tate, N3BXZ

10/9

For Sale:

Fisher X-100
Fisher X-202-b

Heath AA-100
Heath AJ-41
Heath SP-2
Heath PT-1

Sherwood S-5500 Integrated amp
Sherwood S-2200 Tuner

Fisher X-100 Integrated

This an original and great sounding Fisher 6bq5 stereo integrated amplier. NOS power transformer (from the FisherDoc) and new coupling caps. This amp uses a tube rectifier (5ar4). Unit includes a strong set of tubes. No cage. Face has some corrosion and a few of the knob caps are MIA.

$150.00 + shipping

Fisher X-202-b

This is a 7591 integrated amp. It was in a console, so no cabinet. It is in working condtion without hum. Sound is typical Fisher- very good with solid bass, seductive midrange and nice extended treble. Uses ss rectifier- so that dates it to the early- mid '60s.

This unit is sold without 7591 tubes and without knobs.

Transformers are good/ unit would make an ideal rebuild project, or conversion candidate for 6L6GC. Or use the transformers for your own design ?

$80.00 + shipping

Heath AA-100

This is a 7591 integrated unit. This one is in good working condition. Output tubes are NOT included. Vinyl case is not perfect (what looks like a burn mark over the vent fins- on top) and unit is missing screw in feet (I could probably find something that works from the hardware store). The AA-100 also features input sockets under the

chassis. I have listened to this unit at length and the bass is tight with nice midrange and clear extended treble. The transformers in this are some of the best Heath ever used. Tested by John Atwood at 10hz-100khz +/- 3db @8-ohms.

$80.00 + shipping

AJ-41

This is an AM-FM stereo tuner with on board MPX. Unit is quite sensitive with nice sound. On AM, I tuned in WABC-NY; over 900 miles away. I have also listened to the local low power NPR outlet- with nothing more than a strip of wire as the antenna- nice quiet backround. Overall good condtion. Small crack in clear plastic on face- lower right edge.

$110.00 + shipping

Heath SP-2

SP-2 is a "dual mono" stereo preamp. 2 discrete mono channels and common power supply. Printed circuit board for easy parts replacement (and upgrades...). Each channel has its own circuit board, isolated and shielded from the other. With cage, missing one knob. Good working condition (its on as I type this). No hum. Good cosmetic condition. This design is better sounding than a stock Dyna PAS-3.

$135.00 + shipping

Heath PT-1 tuner

This a dual AM-FM MONO tuner with MPX out. The unit works and sounds good on FM- ok on am. I was surprised at the AM sensitivity. If I were to use this one, I would replace some of the tubes and have it aligned. It could also benefit from a good cleaning. With cage and all knobs. Very good cosmetic condition.

$35.00 + shipping

Or both for $160.00 + shipping.

Sherwood S-5500 Integrated amp
Sherwood S-2200 Tuner

S-5500 is a 7591 stereo integrated amp. Unit works well. Sound is fine with solid bass, nice tube midrange and clean treble. No hum. It is in fair cosmetic condition and without case. Output tubes are NOT included.

$80.00 + shipping

S-2200 is labeled as AM-FM-MPX Stereo- but it is MONO. The chassis slot for the MPX board is covered over. Unit can tune AM and FM simultaniously for that early stereo effect. FM sensitvity and sound is fine- AM is not as good. Unit also has a pair of bright and clear

tuning eye tubes (one for each channel). One thing I have noticed in regard to Sherwood tuners is that they are very ruggedly built- just off of the trash heap or garage sale, they are frequently in near perfect alignment are generally usable as-is. This one is no exception. Cosmeticly fine, with some smudgeing of lettering (slight-moderate).

$40.00 + shipping

Please reply to: rl1856@ix.netcom.com

"Absolutely the simplest and easiest" is the W1SL design, as updated in
the book that Steve mentioned above. It's also available from ARRL -
there's a link from my web pages.

As for "best documented", I couldn't possibly comment on that :-)

Apart from the anode and grid line dimensions and a few other details
(all documented), the layout of the W1SL is very free-and-easy. It's
grid-driven, so only requires a few watts of drive, but you can use
damping resistors to absorb more drive if you want. For good linearity
in the driver, you should generally aim to use only about half its rated
maximum PEP output anyway.

OK, guys, it looks like there are several ways to make an anemometer (or whatever you call the things), but *how* do you calibrate one? I don't think a car speedo is that accurate; so I'd like to try something better than the obvious of holding it out the window of the moving car...

I'm not familiar with "snap in" eyelets per se (let me know if you find a source for these!) but eyelets are available from places like Mouser Electronics. They use a flaring tool to stake the eyelets in place. I've used eyelets from International Eyelets in California. To do it right you need to buy their tooling to set the eyelet properly in a press. I've also used the Multicore Copperset kit that inserts thru-hole "bails" into holes. I don't recommend this kit for thru-holes in which component leads must pass through, however. The bails are soldered, not swaged, in place. They can loosen and slide out when trying to solder something like a connector to the board, opening up the connection between top and bottom. Also, it's an expensive kit (approx. $250).

I have a couple solid-state radios which are less than ten years old whose
only use today are as door-stops - each is in need of an IC but of course
the necessary components were custom-made and are now unavailable. Yet my
30 year-old Galaxy GT-550 still purrs, and my 40 year-old Globe Scout
transmitter still burns holes in the ether.

Another company to get eyelets is 'Siska ... 1-800-393-5381' . I think Keystone also carries them, but havn't bought from Keystone for the past year. You need a pad cut out tool, which makes round cut outs around the hole. Put in the eyelet and use an arbor press and tooling to squash the eyelet into place. I also remember you can use a ball pein hammer to set the eyelet, but I think this was part of the Mfg.s staking method ?

>
> the price cop is guilty of incompetence, IMNSHO

A price cop is never incompetent. They just report on the perceived
value in their local market. If somebody has an overpriced thing, they
deserve to have the price cops hooting at them (more on this at the
end of the post).

Don't forget that in a correctly working market, prices rise to the
highest price paid, for any number of reasons. If something won't sell,
its price is too high. If an item is scarce and there are plentiful
buyers, its price is too low if more than one buyer will buy the item
at the asking price. The actual market price falls somewhere in between,
depending on variable such as whether the Dog Star is barking to the
left or to the right.

In this market (Central Texas), $75 for a TU is a JOKE. $10 is actually
high -- the NOS/NIB condition TUs go for $10 to $20, and the ones that
have been in the chicken coop fetch $3 on a good day.

I have to wonder whether the TUs at Green country went home on the same truck
they arrived on.

Jim N6OTQ

Oh yeah, if anybody is interested, I have a 1942 ARRL Handbook
I'll sell for $2,500. Hoot all you want.

The only time AM modulation will occur is during the rise and fall time of the
square wave. The use of the square wave is a form of pulse modulation.
There must be constant change for AM to take place. AM is the result of a
constantly changing carrier applied to a constantly changing modulating signal.
An interuption(quit changing) in either one results in the ceasing of the AM
process for that period of time.

3353. Help on VHF MMIC amplifier selection

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-10-09 00:00:00 UTC
From: Artur Leung <aleung@ittc.ukans.edu>
Message-ID: <361E1D73.34549EF4@ittc.ukans.edu>
Source record: 78278
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.misc

Hi,

I am working on a FSK transmitter project using the Motorola MC13176 chip and I need to boast its output power to 500mW, and I need suggestion on a MMIC that will do the job.
Here is the requirement: I would really prefer using one low-cost MMIC rather than going for discrete components because using discrete transistors increases production cost (each circuit has to be tuned -- time consuming). The MMIC has to be low cost, requires the least amount of passive components to support it, and has around 30dB of gain & +27dBm output power at 150-170MHz. Mini-Circuits has some nice MMICs for that frequency range. Although they are low cost, requires only three caps and a choke to operate, and have one that has enough gain, the P(1dB) is only +12dBm.
What do you suggest? I am fairly new to the amateur radio society and do not have a handful of information on component selection. Please advise.

Artur

Hi Gang,

I am looking for a "pad cutter tool" that
creates REALLY SMALL diameter pads. My old hand held pad cutter
makes pads that are too LARGE.

Thanks for any sources.

>Stephen Tompsett G8LYB

I don't have that but I do have the RSGB "VHF UHF Manual" which has a classic
4CX250 dual design on page 5.94. I am looking for absolutely the simplest,
easiest, and best documented twin 144Mhz 4CX250 design. I have a few as well as
the sockets and chimneys. Most of the other designs are overly complex or
not well documented(IMHO). Is there a better design? I have 10-15 watts drive.

Thanks,
K7YO

HAM stuff for sale:

Ten -Tec Digital Century 21 HF CW Transceiver
80 - 10 Meters, no WARC bands
75 watts input, ~35 watts output CW
Digital frequency display, RIT, switchable audio CW filter
Direct conversion receiver
Built-in AC supply or runs on external 12 vDC

Good condition, slight wear, everything works.
Offset and Tune buttons replaced with R/S buttons.
Slight corrosion near Calibrator jack on rear.
With manual

$175.00 OBO

Computer stuff for sale:

Rolodex REX PC companion
256K, leather case
TrueSync software
With disks, manual, box, extra batteries
Good condition, slight wear, everything works
$60.00 OBO

Accton EtherPocket-SP Ethernet parallel port adapter
Switchable 10baseT (twisted pair) or 10base2 (coax) Ethernet adapter
With manual, disks, and AC wall cube supply
$40.00 OBO

Microcom Travelporte pocket modem
14.4 K data/fax, MNP-10
runs on battery or AC power
with RS-232 cable and AC wall cube supply
$30.00 OBO

If memory serves, we used to use these when a socket for a removable part such as an IC or capacitor was required, and a standard PCB socket would not work.

The manufacturer, as I recall, was Augat. The sockets themselves came on a kind of perfboard. A small tool was used to press these sockets, one at a time, into the plated-thru hole. They could then be carefully soldered on the bottom of the PCB if required.

I have a serious problem with McGill's administration and I need your immediate assistance.

I am a student in the Chartered Accounting Department at McGill University.

On October 1, 1996, I started working at McGill University's Center for International Management Studies (IMS) to reconcile funds provided by the World Bank to the University.

However, I noticed that McGill's administration had been manipulating the accounts and falsifying the reports. The manipulations amount in the hundreds of thousands of dollars.

When I reported what I saw to the University's Internal Audit and to Professor Bernard Shapiro (McGill's Principal and Vice-Chancellor), the University expelled me from the CA program, claiming that I failed my exams. I wrote excellent exams, but McGill rigged the marking to stop me from reporting what I saw at IMS. Please contact Professor Shapiro at SHAPIRO@UMS1.LAN.MCGILL.CA and ask him why the university rigged my marks.

I tried to settle the matter with the University's Ombudsperson, Mrs. Estelle Hopmeyer and with the Legal Clinic director, Mr. Alex Pless, without success. When I went to see Mr. Pless, the University's security hastily dragged me outside the University. This action is a gross breach of the University's own Charter of Students' Rights which allows me to contact Mr. Pless.

My conflict with McGill's administration reached the University's Board of Governors and Audit and Finance Committee, but nobody listened to me.

I lodged complaints against the chairmen of McGill's Board of Governors and Audit and Finance Committee with Quebec's Order of Chartered Accountants, since the chairmen of the above committees are both CAs. However, I was given a mock hearing at the Order, and the President of the Committee on Discipline ruled, unjustly and unfairly, in favor of McGill's chairmen. You can understand why, can't you? You could confirm the details with Mr. Nicholas Chagnon V.P. Publications.

The lawyers whom I contacted so far are not defending me. I suspect that the Dean of Students Professor Rosalie Jukier is influencing these lawyers not to defend me. Please go to the office of the Dean of Students and ask her why is she stopping my lawyers from defending me.

To silence me, a collaborating judge ruled that I may not contact anybody at McGill. He also ruled that I am not allowed to be on the University's campus, although I did nothing wrong. You must contact me to see my evidence about the funds manipulations at IMS and to reestablish justice at McGill.

The University sent me to jail although I am innocent of the harassment charge which Dr. Lees is accusing me of. Dr. Lees sent me to Riviere des Prairies Psychiatric Detention Center, alleging that I have been harassing the university's staffs. This is not true, since I was only questioning the staffs about the suspicious funds manipulations.

Now I am out of work, cannot continue my education, and the University is suing me for criminal harassment. The court ordered that I undergo mental evaluation. A conspiring psychiatrist alleged that I suffer from delusional disorder of grandiose type. This is a lie that is intended to silence me. Will you help me report my psychiatrist to the appropriate authorities?

You might want to confirm the above facts with McGill's Secretary-General, Dr. Victoria Lees at: LEES@UMS1.LAN.MCGILL.CA, but I advise you not to, because she will give you false answers.

Other strange events happened, and I will tell it all to you after you contact me. I request that you communicate with the University's reporters, student groups, the students in the CA department and your colleagues to expose the World Bank funds conspiracy at IMS.

This could happen to you or to your friends, so you must help me put an end to McGill's injustices. Also, I need your assistance. My family and I are in a desperate situation because of McGill's emotional and financial pressures. Would you help us in this respect?

Please respond and take action. Thank you for your collaboration.

well... if she has 1 billion in her pocket and pass it to the lawyer
whomever you hire... what happens ? probably you shouldn't think
of lawyers but just to take this university court directly. It [this
university...] is ridiculous. I have enough evidence to win court
battle.

yep. they will do whatever they can do to prevent you from finding
out the evidence. Thanks for your post. I will be using this as
well to kick this university's staffs out of their administrations.

****
I talked with one of the students here and he told me that professor
changed the course outline after the final exam is written. That's
not acceptable. (i.e. changing the final exam weight from 50% to
2/3 of final mark). It is ridiculous. Just keep up posting and
I will post my stories also.
****

: Any hints for sources?
: Thanks, 73, W6MIK

I built one using an old ceiling flouresence light fixture that had two 40 watt bulbs. Just turn it over and mount it on some 2X4 legs, put a piece of glass on it for strength and a few layers of white paper under the glass to reduce the amount of light.

Source record: 78200

Cutting "really small" pads (e.g., 40 mils or less) would be difficult
at best since hand movement (rocking from side to side, etc.) would
cause the cutting edge to dig into the desired pad and would probably
lift it off of the board. Also, the index pin in the center, which
naturally would have to be smaller, would be more susceptable to
breakage.

I seem to recall that someone made a pad cutting tool that mounted in
a small (AND STABLE) drill press but the name escapes me. You may need
to bite the bullet and have a board made.

I looked on the lpkf web site (www.lpkf.de) for their soldermask feature. Under Tools and Accessories look for LPKF EasySolder. There's a picture and a brief description but not much more. Contact LPKF for more details. I assume it's some kind of foil sheet that you mill and then adhere to the board.

Take care,

Mark

3371. HELP:DG-5 Freq..Display

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-10-10 00:00:00 UTC
From: email@tig.com.au
Message-ID: <6vncau$j7h$1@toto.tig.com.au>
Source record: 78202
Cross-posted to: rec.radio.amateur.equipment,rec.radio.amateur.homebrew,rec.radio.cb

My kenwood DG-5 digital display seems to be out by 100 hz or so on both receive and transmit.
can anyone please tell me how to adjust this so that the freq... would be correct. ??

i noticed on the bottom of the DG-5 there is a hole in the cover near the back that allows me access to a screw with a screwdriver slot for adjustment.

will this ajust the readout ?

any help greatly appreciated .

please email me at email@tig.com.au

thanks.

There is an MMIC made by HP that has a P1dB of +27dBM, HP part no. MSA-1023 (I think it is a new part). It appears to be useful from 100Mhz to 2Ghz. The device has 25 ohm input and output impedances and is designed to be used in push-pull, although it can be used as a single-ended amp. This is the only MMIC I know of that is rated for that kind of power. Anyone else know of other high-powered MMICs?

Any one have info on a JH 100 frequency counter?

I just bought it for my Kenwood TS820. It plugs into the IF out. The
name on the front of it is JH 100 and it has two band positions, one for

80/160 and the other for 40 and up.

The guy I bought it from says it came with his TS 820 when he bought it
but doesn't know anything else about it.

Any help much appreciated!

Yes -- the capacitor adjustment visible in the hole is for the reference oscillator in the counter. First calibrate your rig to WWV as per the rig's manual. Do not look at the counter -- just calaibrate the rig. Once the rig is calibrated, adjust the capacitor on the counter to the frequency to which the rig is tuned. This is quick and simple. After performing this adjustment, get someone who "knows his stuff" on the air -- preferably someone with a good rig that will read frequency accurately, and confirm your adjustments. I run a DG5 with a TS520S and have performed this procedure with excellent results.

Message-ID: <01bdf4e5$dfc59d00$LocalHost@default>
Source record: 78214

COMPLETE ANALYSIS OF COAXIAL LINES - 50Hz to 1GHz

This program allows the user to design/specify the line, compute all primary and secondary constants, to terminate the line with any complex value impedance between open circuit and short circuit, and compute the line's input impedance, from power frequencies up to UHF.

Impedances are displayed in the form of R + jX, the equivalent parallel form, and as the impedance modulus and angle.

Input data includes characteristic impedance, inner conductor diameter and propagation Velocity Factor. Output data is displayed in a form appropriate for the radio frequency spectrum.

Program users will be more familiar with Zo and VF than capacitance and permittivity. VF can be easily and accurately determined on a short length of line by measuring its resonant frequencies. Diameter over the insulant is a computed value forced by the program to correspond to the inputted values of Zo and VF. Thus, if a sample of line is available the validity of input data can be verified by measuring the actual diameter over the insulant.

Computed performance data includes reflection coefficient, VSWR at termination and at input to line, matched loss and actual loss in dB. Actual loss is also shown in the form of percent of input power lost in the line. The Quality Factor Q is computed for use when a section of line is to be used as a capacitative or inductive impedance.

Some sentences in the last 2 pages of operating notes actually apply to twin balanced line. Unfortunately, in the last few minutes of writing the program the source code was accidentally erased - lost and gone for ever! So it is impossible to correct the text. I had intended to add a note on using the program to design 1/4-wave and similar transformers. So far as I am aware there are no bugs in the maths or display of input/output data.

Now download it in a few seconds. Not zipped up. Can be run immediately - and discover in a user-friendly manner what really makes coaxial transmission lines tick.

Click below.

Sounds similar to a circuit I built back in college lab 15 years ago. The idea was a magnet mounted on the spokes (a fan in your case), swinging by a small coil on the forks would count revolutions for a given time period. (Kinda like Roy's idea). I used a Programable ROM - but you could probably find the right ic's out there. The concept is just like they're making bike speedometers these days. You might want to take a look a them down at the bike shop if you're not familiar with them. Calibration is still the problem. I rather like the idea of hanging it out a car window.
I've got an old one with a dim LED you can have if you happen to have a U5 RCA tube for my old Belknap radio...

Hi all,

I'm trying to find a little 2" 'belt drive' (the rubber belt that drives the capstan motor) for a cassette recorder, but can't seem to find an outlet that sells them. Can someone offer any suggestions?

I used to pick them up at Radio Shack - but they don't carry them any longer...

Email please - Thanks.

John

Homebrew RF-Deck uses pair 4-125's, about 500W out needs HV supply:
$150.00

Thoradson Plate Xformer 1.2KV @ 1A: $50.00

Unbuilt Head Coax-Switch $60.00

Heathkig IG-102 RF Signal Generator: $30.00

Heathkit DX-60B w/matching HG-10 VFO: $130.00

MFJ 752C Signal Enhancer: $40.00

Heathkit AM-2 Swr Meter: $15.00

Pair Collis Motorized Roller Inductors $80.00

Pair of HTX-202 2M HT's with hand mic., exec cond: $75.00 ea

Kenwood TS-930SAT w/250hz CW filter, auto tuner, etc... exec condition:
$900.00

Linear Amp Parts (sold as set, will not split): Pair of 4CX1500B medical
pulls, w/1-Socket/Chimney,
Peter W. Dahl Plate transformer a 115/230 VAC primary and a 1250 VAC @
1.5A CCS secondary
8-1500mfd @ 450V Computer Grade caps, pair of 6KV block diodes,
pair of ducted blower fans (pulls from military equipment) all for $450.

Ham-IV Rotor & Controller $200.00

Above prices do not include shipping. E-mail direct if interested:

3401. SX-28A help

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-10-11 00:00:00 UTC
From: Joe Schreiber <jschreiber@netcarrier.com>
Message-ID: <6vqnnb$7it$1@supernews.com>
Source record: 78230

Hi,

Any SX28 experts here? I'm trying to revive a dead SX28A. The only thing coming out of the speaker is internal noise. A 455kHz (400hz modulated) signal injected to pins 4&5 of the detector will produce a nice, clean tone. The same signal injected at the plate of the second IF tube (6SK7) will produce the same tone, but at a lower amplitude. One of the capacitors of T3 peaks nicely, but the other one appears to have little or no effect. As I move the signal injection point further upstream, the tone at the speaker gets weaker, and I need to increase the amplitude of the signal generator. Injecting the signal at the plate of the detector (6SA7), I need full power (3V p-p) just to get a barely audible tone at the speaker. One of the coils in T1, and one of the coils in T2 peak nicely... the others don't have much effect. I cannot get any tone from injecting an RF signal to the grid (pin 8) of the mixer and tuning the receiver to that frequency. The output of the local oscillator appears to be OK. Also, injecting a 455 kHz signal into the earlier stages of the IF will only produce a signal when the AVC is turned on, and not when AVC is off. Injecting the signal at the detector, however, will produce a tone with the AVC on or off. Any help would be appreciated.

Thanks,
Joe

I suppose one could crunch up a modern glass diode and use the tiny bit of silicon or germanium left attached to the lead, one could also use the tiny "cat's whisker" left on the other lead - but heck - why bother crunching it up...

There is a chain store "Natural Wonders" where one can find Galena, Iron Pyrite, and reject/waste silicon for just a few bucks. Some craft stores also handle small mineral samples...

I've never tried to use it to measure wind speed, but here's a device
I used to measuring cooling air in electronic enclosures.
Build yourself a bridge with a pair of resistors on one side and a pair
of small light bulbs on the other.
If you're careful, you can squeeze the glass bulb in a vise to remove
the glass envelope without busting the filament. Took me several tries.
So, you've got one bulb with glass and one without. Mount them side by
side
in the wind and you've got a hot wire anemometer.
Have no idea what happens when it gets dirty.
miker

Various variations on this idea will work. An old reliable for measuring low to moderate wind speeds was a thermopile. Basically, just a heated resistor; kind of like a hot-wire anemometer with a lot of mass. Its response wasn't as fast, but it didn't have as much problem with getting dirty, as Miker alludes to.

What this means is that you could use just a resistor. Run enough current to warm it up a bit, and monitor the change in current/resistance as the wind blows by to cool it.

You don't need to calculate how it works. Just take it out for a drive sticking out the window of your car, and calibrate the response vs speed. Drive up the road, and then back down, and take the average, to factor out any "real" wind.

I found some socket pairs at a hamfest that no one would buy because they were for UHF. These were really nice sockets on a Silver plated base. I bought 4 of them at $5.00 each. I just put a screen cap on the base pin and they worked fine on 10 and 6. I am not interested in selling them but don't pass any by just because they are for UHF.

Many years ago I got a Heathkit unit for my parents, and was impressed by the simplicity of the method. There's a little fixture holding, as I recall, four magnets on the shaft which the cups turn. They go by a single reed switch. In the indoor unit there's a one-shot with a fixed time interval. The unit simply counts the number of switch closures occurring in the time interval and displays it as a number representing the wind speed in the chosen units. The time interval is adjusted to calibrate the unit, and is changed with a switch to make the readout represent speed in mi/h, km/h, or knots. The whole thing used just a few TTL ICs.

Hey Chuck! Sure hope you share what you find!

Have you E-mailed the folks at the Hurricane Net site? They might have some leads, or may be interested in recommending what you design to folks in hurricane-prone regions whose gear keeps going down when most needed!

BTW: How would you measure speed with ic chips? Are you thinking of using a light beam through a notch in a rod on the anemometer across to a light sensor?

What about calibrated barometric pressure? Temp? Humidity?

If you know a backpacker, hunter, boater, or hobbyist who has a GPS receiver, drive on a straight road (on a calm day!) and look at the speed reported by the GPS. That'll get you within about 1 MPH. This limitation is due to the "selective availability" variation. Differential GPS systems are getting more common now, and if you can find one of these to borrow, you should be able to easily get within a fraction of a MPH. What kind of accuracy are you looking for?

Well, nobody wanted the PBX telephone network thing.. so I dismantled it!
Now I have a million cards with ic's, cpu's, led's and dandy little
switches! the big thing is a nice self-contained power supply which I tested
at 52volts DC! I'm hoping it is an amp monster, too...
It is an Executone Enterprise PBX, removed power supply is about waist high,
all heatsink inside, 60lbs, 3blade fuses everywhere... and caps the size of
a pepsi can. has 'alarm' led for what I assume to be a fault protect,
117vac with sticker on back saying series 2 and ps-a?? vom says 52vdc at the
terminals.
Question: anybody know about this thing and how to turn it
down/convert/resist/whatever to 13.8? how to test amperage output without
blowing something up? Hams dream supply or welder? help!!
thanks!
Randy

3422. high level tube mixer question

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-10-12 00:00:00 UTC
From: ea154@cleveland.Freenet.Edu
Message-ID: <6vsiai$238$1@alexander.INS.CWRU.Edu>
Source record: 78153

Hi everyone, hopefully i'm in the right place to post this.. but here goes. i have a somewhat decent knowledge with tubes but i'm stumped on this one, i was looking at mixer schematics and comming up with some ideas and looking at the high-level tube mixers shows one for about 1296mhz at around 15W, so i thoulght to myself, ok this could be fun to experiment with so i went to look up the tube info so i could get an idea of what kind of power supply to use, well turns out i don't have the tube it calls for (what a shock) but the ratings on it (2C39) show "freq. MHZ full ratings 500mhz" ok, how can this tube put out almost full power at over twice the frequency rating for it? like theoreticly speaking i could take a tube (triode i believe) with a maximum freq. of 54mhz and use it as a mixer for 108mhz? if someone could explain this to me it would be greatly appreciated since i'm having no luck finding an explanation in any texts.
tnx, Josh

3423. Re: 4CX250 Grounded Grid Amp

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-10-12 00:00:00 UTC
From: Mike Willis <"M.J.Willis "@rl.ac.uk>
Message-ID: <3621B3B7.67515421@rl.ac.uk>
Source record: 78154

Indeed, use the W2GN - but if you want the simplest easiest amplifier, a single 4CX400 might be enough. There are plenty of designs - for example the one in the ARRL
handbook for the 8938. I built one using a 4CX250B. Exceeding the ratings and putting 2500V
on the poor 250B yeilded 400W of output. The 8938 ought to be able to manage 500W within
its ratings. This is nearly as good as a pair of 250Bs but with less effort.

Hello, Joe--
It's possible that DC leakage is occurring through the last IF
transformer, either due to contaminants on the IF transformer's internal
insulators or leakage across a trimmer cap (if one side is at B+ and the
other at grid or ground pontential. The positive DC effectively biases
th AGC high and decreases sensitivity.

While I've encountered this effect (IF tranny DC leakage) in more-modern
IFT designs, it's worth a look. Disconnect the secondary completely,
apply power and measure from the secondary winding to ground with a
VTVM. ANY positive DC is a sign of trouble.

73,
Brad AA1IP

3425. Re: Through-hole plating

Many of the old Dynaco hifi kits used eyelets at wire connection points. Unfortunately, the connection between these eyelets and the circuit traces would become intermittent after a few years. Unless you are certain that newer eyelet technology has solved the problem, I'd strongly recommend that you solder the eyelets to the circuit traces on both sides of the board. It's much easier to do when the board is new than 10 years later when the eyelets and circuit traces become tarnished.

There are at least 3 ways to measure wind speed. You can use a spinning thingy with some sort of revolution counter, photo chopper, Hall effect, etc, or you can use the hot wire method, or you can use doppler measurement. Others have outlined the other methods, so I'll talk about the doppler method.

This requires an ultrasonic source and receiver (scavenged from old pre-IR TV remote conntrols for example). Space them about 3 feet apart on a vane so that they align with the wind direction. Compare the received ultrasound with the source using a phase detector, and the phase shift is the doppler due to wind speed. You can calculate this directly from the doppler formula, so calibration doesn't require driving around with it hanging out of a car as the other methods do.

I have wanted to try this Doppler method but with one sending unit and three or four receiving units. the receivers would be arranged around the sending unit. this would permit the detection of direction as well as speed. Maybe some day when I run out of projects :-)

I have two roller inductors. Both Porcelain. One is a very large unit capable of handling very large power. The roller is 9.5" long and 3.5" wide, it has about 80 turns of wire. The contact rides on a glass rod. Very smooth turning, and in excellent condition. It will handle from broadcast band all the way up past 30MHz. This would be great for a large amp or a large antenna tuner. $175 shipped.
The second Roller is much smaller but equally the same quality. The roller measures 4" long by 2" wide with 24 turns of wire. This would be great for a smaller tuner or transmitter up to a KW+. $75. Both these roller inductors are in excellent shape. I just changed my mind on the project I was working on. 73 Chris VE3NGW/W4 Florida

OK, people have suggested various ideas about microswitches & magnets, hot wire anemometers, and even ultrasonic doppler. For the "no moving parts" type, the hot wire method is probably the easiest, but generally requires a lot of power to keep those wires hot.

For a simple low power version, using an op-amp and some LM334 current sources (used as temperature sensors), complete with a schematic, see: "Electronic Design" magazine, May 25, 1998, Pg. 116.

There's an article by W. Stephen Woodward titled: "Low-Power Thermal Airspeed Sensor". Looks pretty simple to build and use. I intend to build a version myself, but due to work getting in the way, I haven't had the time yet. I don't know if this is available on-line anywhere, but the author's E-mail address is woodward@net.chem.unc.edu

You might see if he has an electronic version of the schematic & article.

Source record: 78161

Anyone know how the ALC input pin #6 ACC socket works? Tried to connect this input to the ALC output from a PA. Output from the PA was max -12V so I used a resistive divider (10k + 4.7k) to get the voltage down to max -4V. According to the manual the input impedance is at least 10k butI got basically 0V after the divider. Even tried a direct connection via 4.7k with the same resï¿½lt.
The ALC input seems to be some active device.

Am I missing something on using a resister heated up and changing value while you drive your car down the road. Lets say, you apply a fixed amount of voltage and current across the resistor and drive down the road and take some measurments. Today the outside temp is 70 degrees and tomorrow the outside temp is 35 degrees. I guess you would have to calibrate for each degree of temperature change as well. That would sure keep you busy. I enjoy ham radio when it is actually getting to know other
hams on the air and being able to run into them more than
once..

I am very active on 80 and 40 meter pactor/gtor and find
this mode very condusive to a long-winded "let's share war
stories" type of operation. I am not into contesting, but if
you are, then that's your niche in ham radio. Personally,
exchanging signal strength reports and qsl information, only
to run off and do the same to the next station seems a waste
of spectrum resources...

Not to mention, that most of these are robots.

Basically the whole disease is what General Patton referred
to as "paper hangers."

That is, people who's sole lease on life is to accumulate paper
to hang on the wall. The extreme being people who belong to
Mensa type organizations. If their IQ was so high, they must
realize how stupid the whole idea sounds. But that isn't the
case.

There's four things to hang on your wall: 1) Your High School
Diploma, 2) Your College Bachelors Degree, 3) Your College
Masters Degree, and 4) Your Doctorate.

Everything else is akin to mowing the lawn...

Steve

Actually, you probably should hang your station license there so
you don't forget to renew it in time.

But then again, I don't know why you'd waste space with the above when
you could put other things that are more meaningful up instead.
(like photos of places you'd like to return to, awards from other
parts of your life, a poster or two......)

I don't know how much "that" is, but most car speedometers are "pretty"
accurate. I've seen many calibrations that show 1 mph error at 60 mph.
This method -- calibration against a car's speedometer -- has been
widely used, in fact. If you want better quality results, you can
always precalibrate the auto's speedometer by driving down a road and
timing the trip between mile markers while running at a steady speed.

Won't this method also require lots of corrections? It seems to me the phase shift will depend on barometric pressure or altitude and perhaps on humidity, temperature, or precipitation (though several of those are inter-related).

Curses! I've been caught!

You haven't missed a thing, Van. Good thermal methods (hot-wire, hot-film, thermopile, etc.) need to be corrected for temperature if it varies too much. They also need to be corrected for altitude if that varies too much.

But you don't need to calibrate at all the possible temperatures. You can correct "theoretically" (the right IC's will do this for you automatically) or you can use a two-resistor setup with one heated and the other not heated.

The 11C90 has been gone for a couple of years...it was a lousy chip anyway; ran so hot it'd sizzle if touched with a wet finger. Well, maybe not that bad, but there's a better chip if you can find it... the Motorola MC12080. Good to 1.1 GHz and only draws about 10 mA at 5 VDC. However, it's low end is limited to about 100 MHz if fed with a sinusoidal, almost DC if fed with a sharp-edged square wave. You can prevent it from self-oscillating (it's very sensitive) by pulling the inputs apart by about 50 mV...one easy way is about 910K ohms from IN and IN/ to Vcc and ground. Mine will "see" my 350 mW DS-S41 450 MHz handi-scratchi from fifteen feet or so with a rubber ducky on the prescaler input.

If you're just looking to count to 100 MHz, a lot of the modern logic families can do it such as the FAST family (74FXXX); the 74F74 will clock to 100 MHz. However, I'd look on the swap lists for a ready-made counter and build a prescaler in front of it. I bought a Beckman UC10 (good to 125 MHz) for < $75. Building a counter will probably cost you more in parts, cabinet, hassles and solder flux fumes.

3442. Source for good 10 MHz TCXO or OCXO modules?

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-10-12 00:00:00 UTC
From: davem@groucho.cs.ubc.ca
Message-ID: <6vtps0$pu3@groucho.cs.ubc.ca>
Source record: 78173

I have a frequency counter that works well, except that the timebase oscillator is a plain crystal that drifts a significant amount with room temperature changes, as well as during instrument warmup.

The counter is capable of resolving 0.01 PPM (1 part in 1e-8), and I have a GPS with 1 PPS output that I can use to calibrate the counter to an accuracy of at least 0.1 PPM, but the timebase itself drifts by about 1 PPM. This is frustrating.

I'd like to replace the timebase with an oscillator that is stable to within about 0.1 PPM over a range of room temperatures. A TCXO (temperature compensated crystal oscillator) seems like the best choice, since it should be pretty accurate immediately after turnon, without waiting for it to warm up. An OCXO (oven controlled crystal oscillator) would be even more stable, but needs extra power for the oven (which the counter power supply may not have) and takes a while to warm up.

Rakon seems to make a nice collection of TCXOs, and I note that several makers of GPS receivers use Rakon TXO 4080Es as their master oscillator, so they must be decent performance. But I've been unable to find anyone who actually *distributes* these, and don't know how expensive they are.

I'd appreciate pointers to someone who sells the Rakon oscillators, or other TCXOs with the necessary performance. Frequency must be 10.000000 MHz for compatibility with the counter's existing firmware.

Places to find surplus or used 10 MHz TCXOs would also be welcome.

Okay, here's where it's at: I have a slick little radio, an SGC 20-20.
I use it for camping, and some mobile operation. Since it puts out 20 watts
but can be set as low as a few watts I thought I'd like to hook it up
ocassionally to a small amp. HOWEVER--I don't want to use a Palomar brick
or some other such device mainly because of the lack of tuned input
circuits. I guess the ultimate answer would be finding a Ten-Tec amp. that
would have been used in conjunction with some of the early Argonauts. Of
course everybody and his mother is looking for such a gem.
So if anyone knows of any definitive articles in old QSTs or the like
that have plans for building such an amp could you send me the info on issue
number. etc. I'm not looking for a huge amount of output--about 100-150
watts. Of course you ask, why not just get a typical rig like a Kenwood,
Yaesu, or Icom? Nope, they're not for me. I'm tired of ricebox radios with
their dozens of features that I don't use. I just want to keep it simple
and basic.

Thanks,
Mark--KF8KL

>anyway; ran so hot it'd sizzle if touched with a wet finger. Well,
[snip]

The CA3179 prescaler chip works to at least 1000 MHz. The only drawback is that it is a divide-by-256 and requires oddball crystals for the counter. But it has plenty of sensitivity.

There was an article in Radio-Electronics magazine years ago for a frequency counter that used the Intersil ICM7216DIPI counter chip and the CA3179 prescaler. I built it and am still using it. The circuit required a 3.90625 MHz crystal for the 7216.

I know of some different methods for what you want to do, Some better for different circumstances. Let me know how (handheld, mobil, fieldday,etc...) you want to use amp.
Input Power. Antenna Options.

How about 8- 2sc2879 transistors for 800W Loafing.... I got a Negative that I can scan for ya....

The BEST LITERATURE for "Understanding HF amps", http://www.rfparts.com has a "Mobile Amplifier Plan Set" Part # CAOML
It's for a larger amp, but it is like a "Heathkit" manual... You'll actually understand what's happening in that Pile of Aluminum, Copper & Silicon...
I Highly suggest it for A Primer.

ARRL Handbook has plans for what your looking for, but w/ 2 "Tab" type transistors...
Just let me know....
I'll find what you need...

Ed Grafton

Hello,

find some recent back issues of Electronics Now or Radio Electronics,
on of the had a similar project, but I can't remember which one. The
project used the cooling of wind passing over two transistors to
detirmine wind speed. I believe the project was fetured in the last
year or so.

Source record: 78186

If you're going to suggest the CA3179, with it's high division ratio,
then there are other possibilities that might be closer at hand.

TV sets and VCR's with phase-locked tuning, will have prescalers. Cab3el
converters might have them too. They will have high a high division,
which may or may not be acceptable to a given application. But you
can often find them in the garbage, or at giveaway prices at garage sales
and hamfests. They are simple, so it should be possible to get the
pinouts by tracing out the circuit around the IC.

Cellular phones will likewise have prescalers. I picked up one at
a church rummage sale for fifty cents, and then bought another one this
past summer for five dollars. Both were the old bulkier style. I was
able to get information on one of the prescalers by doing a websearch
(I knew it was a Plessey, but couldn't find it at the Plessey site, but
a websearch turned up the part number on some other website, where an
equivalent wsa listed). It has a bigger division than 10, but it
was smaller than 256. I haven't decoded the prescaler in the other phone.
You should be able to get two prescalers in each phone. They will be good
up to at least the range where cell phones operate. And you can pull
other useful parts out of a scrap cell phone (the older ones have the
advantage besides low cost of using larger parts) such as a TCXO, and an
FM IF strip (both of the phones I bought had first IF filters in the 80MHz
range).

Digitally tuned car radios will also have a prescaler. The ones I've
looked at all use a separate IC to prescale the output from the FM tuner.
They will have a higher than ten division, though I can't remember exactly
what the figure is. I also don't know if they ae any good for frequencies
much beyond the FM band, I haven't seen any specs, so these may not be
a better choice than simply using fast 7400 series logic.

Last time I talked to CEL, they told me those prescalers were being
phased out of their product line. Maybe that's not true after all?
Would be nice.

The Motorola MC10EL33 / MC100EL33 is also a decent alternative, as is
the older and cheaper MC12074.

It wasn't a problem for just Dynaco. RCA, Magnavox and GE used eyelets in
their televisions and they were a constant source of problems there, too.
And the GE sets had the eyelets soldered on both sides of the boards.

Depending on the bandwidth of your 'scope and the frequency that you're operating at, you may be able to get by with just putting a sense antenna on the vertical input. Try doing the simplest things first.

I don't know about in the US, but the Active chain in Canada is expensive- like radio shack with a wider selection. I have found that with many orders it is cheaper to go with Mouser electronics (mail order) and have it delivered UPS red/blue for ASAP... even with shipping to Canada, it sometimes comes out $5 - $10 cheaper on some $60 orders, including shipping. I'd check it out- http://www.mouser.com

Just a thought. ;-)

Looking for a schematic for the LUNAR PAG-144 preamp.
Called Lunar and he was suppose to fax me a copy of the schematic but never did. Acted as if it really ticked him off when I even asked for it.
If you can attach it to a message that would be fine, if not the address is :

Johnny Carter
P.O. Box 18
Deanville, Tx. 77852

Thanks for the help.

How can you be sure its not a 25v PA transformer?

It would still be useless as plate-to-speaker transformer, but both
variations are supposed to work in place of a 600 ohm to 8 ohm matching
transformer for use with your boatanchor recievers.

I can't think of one with those specs. There are a few wideband amps
that have the gain, but not the cheap MMICs. The most gain I've seen in
the MMICs is about 20 dB. You will probably need two MMICs to get the
numbers you want. You will need to bypass the heck out of the power
supply because they will oscillate quite well at low frequency through
that path.

Here are some suggestions, north to south, your milage may vary.

Electronics Supply is now somewhere on Hwy 99, near the Half Price Books store in Lynwood as I interpet their address. (They used to be in Wallingford, west of the U of W, near the Dick's Drivein burger joint). Havn't gotten to their current location. I found the address on the http://www.nteinc.com web site. More specialized for repair parts, but they had a wide variety of stuff. (My usual place for TV repair parts, which I havn't needed for a while).

Electronic Mall, Lynwood, north of 196th, a couple of blocks east of Hwy 99, near Scriber Lake Park. (Address in the yellow pages). Where the old United Products surplus store ended up, only there's no surplus junk anymore.

ABC Communications ???, 15th NE and 175 NE (King County). Used to be a ham and CB radio store, havn't had a reason to go back there for a long time.

Radio Steve's Old Technology Shop. Green Lake area, between the Chubby and Tubby and the Twin Teepees. Antique radios and tools. irregular hours.

Radar, Inc. Seattle, north of downtown, below the Seattle Center off the waterfront. (Elliot and John St?) (Has a web site, www.radarinc.com, I think). Regional electronics distributor, but has room of surplus stuff too.

Active Electronics. Bellevue 13107 Northup Way. (Just south of Hwy 520 in the industrial slums of Bellevue). The component shelves of a Radio Shack on Steroids. The retail arm of Future, a big canadian distributor.

Vetco. the building just west of Active. The area's modern surplus electronics store. PC's, Test Equipment, components.

Supertronix, Kent, On the West Vally Highway, across the highway and just north of Boeing aerospace. (186th SE? 189th?). Another Radio Shack on Steroids, a retail arm of one of the local distributors. Has some Amidon stock (torroids and stuff).

Boeing Surplus, just cause you'd be down there.

Electronic Dimensions, Tacoma, the area's old surplus store. strange stuff.

Why are you looking for a tuned-input solid-state amplifier? Is there
some specific feature you require or some technical issue that you're
concerned about?

> So if anyone knows of any definitive articles in old QSTs or the like
> that have plans for building such an amp could you send me the info on issue

> Yaesu, or Icom? Nope, they're not for me. I'm tired of ricebox radios with
> their dozens of features that I don't use. I just want to keep it simple
> and basic.

I guess you haven't looked very hard at those "ricebox" radios. There are
some rather attractive, inexpensive rigs like the Yaesu FT-600 (commercial
grade) or ICOM IC-707, both of which feature comparable, if not superior,
receiver performance relative to the SGC-2020 (according to the QST
reviews). These radios don't have a lot of features, and excellent
basic performance. What is your issue with them again?

Mouser is now selling CEL/NEC RF components; I find the price reasonable
They have 4 or 5 prescalers. Recently, I have used the Divide by 2/4/8
with good success; it is the UPB1509GV, it does work with sinewaves
from 50 to 1000 Mhz. I have also used the UPB1506GV which divides by
64/128/256 from 50 Mhz to3000 Mhz. They both come in the SSOP package
only. Regards! Yvon. VE2AUC

Subject: ** FLEA at MIT ** Sunday October 18th Cambridge MA
Summary: Buy Sell SWAP Ham Radio Electronics Computers 9AM - 2PM

This coming Sunday... The Season's LAST....

*** !!!! In our Traditional GARAGE and lot !!!! ****
so come rain or shine or super heat the Flea is on !!!

********* $1 buyers discount with hardcopy of this notice ********

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday October 18th 1998
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $4 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $10.00-each at the gate.

The flea will be held at the corner of Albany and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up
time starting at 7AM.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered
well illuminated tailgate area is available for all
sellers (6'8" clearance).

Talk-in: 146.52 and W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)
MIT Radio Society (W1MX)
Harvard Wireless Club (W1AF)

For more info / advanced reservations 617 253 3776

3478. Re: SX-28A help

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-10-13 00:00:00 UTC
From: Xjshillw6ivw@earthlink.net
Message-ID: <3622f253.56102167@news.earthlink.net>
Source record: 78101

Joe: I'm not an SX-28 expert, but would like to offer a few
suggestions:

1. If you want to tweak the adjustments of an IF transformer, inject a
signal at the grid of the previous tube, not the plate. For example,
inject the signal at the grid (pin 4) of V6 to determine the effects
of adjusting T3. Connecting the signal generator detunes the IF
transformer. When checking the entire IF section, set the signal
generator to the IF frequency, and connect it to pin 8 of the 6SA7. I
would set the receiver to the lowest frequency band, so you would not
have a small coil connected to the grid. Since you have adjusted the
IF transformers, swing the signal generator a little above and below
the IF frequency.
2. Make DC voltage measurement at the various tube socket terminals,
as described in the instruction manual. Capacitors frequently become
leaky and resistors increase in value in old radios like the SX-28.
You might also carefully look at the resistors for discoloration,
which is usually caused by excessive dissipation because another part
is defective, typically a capacitor.

It seems to me that working 100 countries is actually fairly easy given just a modest station and average sunspots. Getting the cards seems to be the devil, and then there's the nuisance of getting them to a checker if you don't happen to live in the USA.(actually, there was an accredited card-checker operating at the RSGB HF convention last weekend, which saved a number of people having to trust sometimes irreplacable records to the post)

DXCC certificates impress me, but chiefly as evidence of the perseverence of the operator and his or her skill in navigating pile-ups. The people with scores approaching the total number of countries that have ever existed have devoted most of their lifetimes to their pursuit, which has to be impressive. I find a station that can run moonbounce SSB just as impressive, I find a homebrew transceiver - especially if it isn't directly built to a published design equally impressive, too. The good thing about this hobby is that people can exert themselves in different ways.

> I wouldn't have had many, if any, meaningful conversations if I had
> spent a half hour per contact, instead of 20 seconds. And the end
> result is all the same. Nobody called me, they called my QSL card...

I'd never thought of that in those terms. That's a startlingly good way of putting it.

Cheers
David GM4ZNX

3483. Seattle area Hams - NEEDED good Electronic store

Is there anybody in the Seattle area that knows of a GOOD electronics Supply store - and Not RIP OFF SHACK Either. I stumbled onto one a few years ago, but havnt built anything in a while and forgot where it is. Im in Everett in the North but am willing to travel down to Seattle for a good supply of caps/resistors/boxes/switches etc etc.

Well Randy, Without actually looking at the supply, I would guess that it is probably good for about 25amps. A lot of the older phone supplies were used to keep a battery string charged as well as run the PBX. On most of the Executone gear, the 48VDC was used on the battery string, and 24VDC (or similar voltage) was used to supply 'talk battery' to the line circuits. If you have been planning to build a solid state linear, this supply (48VDC) may be the 'cat's meow'. I will dig around and see if I have any paper work left on those Executone beasts. 73 de VE6INM

Yes, this is a 70v PA transformer.

The idea, is that the PA amplifier has a relatively high output impedance, providing 70 volts (I've never been clear on whether that's RMS, peak-to-peak, or what...) for an audio bus. This bus is fed in parallel to all speakers. At each speaker, one of these transformers taps the line, using the lugs for the amount of power you want that speaker to take. The secondary taps appropriate for the speaker's impedance are used.

I suppose with some calculations from Watt's and Ohm's law, you could figure out the primary impedances of this thing. My guess would be that it's way too low for use as an audio output transformer in a tube-type circuit.

Well, the main difference is that I don't have to pay to ship my signal
when I work Norway. 40 pounds of tubes cost quite a bit more to get from
Oslo than from Chicago!

I believe its RMS which equates to approximately 100 Volts peak.

Tom, Don't use that transformer in the '101. It is designed for use in a 70V PA system. The taps on the primary are for setting the level on the speaker that will be connected to the 3.2 or 8 ohm secondary. I have a couple old audio output transformers kicking around. What is the primary impedance on the one you need for the old Hot Water rig? E-mail me at ve6inm@aol.com and I will take a look tonite. 73 de VE6INM In article <36228603.21DF@postoffice.worldnet.att.net>, "Tom V." <TVAC@postoffice.worldnet.att.net> wrote:

I have the following for sale, prices do not include shipping. E-mail direct if interested.

Homebrew RF-Deck uses pair 4-125's, about 500W out needs HV supply: $150.00

Unbuilt Heathkit Coax-Switch $60.00

Heathkit DX-60B w/matching HG-10 VFO: $130.00

MFJ 752C Signal Enhancer: $40.00

Heathkit AM-2 Swr Meter: $15.00

Pair Collis Motorized Roller Inductors $80.00

Kenwood TS-930SAT w/250hz CW filter, auto tuner, etc... exec condition: $850.00

Linear Amp Parts (sold as set, will not split): Pair of 4CX1500B medical pulls, w/1-Socket/Chimney,
Peter W. Dahl Plate transformer a 115/230 VAC primary and a 1250 VAC @ 1.5A CCS secondary
8-1500mfd @ 450V Computer Grade caps, pair of 6KV block diodes,
pair of ducted blower fans (pulls from military equipment) all for $450.

The best audio DSP for SSB use that I have found is the JPS NIR-12. It
is much better than the NIR-10. The NIR-10 is better than Timewave
units. These comments apply to SSB with a receiver with good
selectivity.

3499. help with 440 25w amp

Newsgroup: rec.radio.amateur.homebrew
Date: 1998-10-13 00:00:00 UTC
From: af389@lafn.ORG
Message-ID: <362381A9.EB4295F9@lafn.org>
Source record: 78122

Hi Gang,

Appologies to QRP-L group since this is not strictly QRP.
Sorry for such long note.

I am trying to service a 25 watt 3 transistor cascaded
440 RF AMP that only outputs 5 watts but requires 50watts DC power
input. Recently, before I began working on AMP to stabilize, AMP did
output 25 watts with about 60 watts input when driven from 1 watt 440
HT. Something has changed. I need help diagnosing
before I buy expensive replacement RF power transistor.

Output stage and Heatsink get hot FAST.

Output appears to not be able to resonant near 440mhz. Final stage is
broadband so cannot measure resonant freq, actually do know how to
measure with my limited test equipment.

Rather than use BW of these lists, private email is prefered.
There is more to story. Schematic is available as JPG file.

Thanks for any help. Glad to share findings with the list.

The speed of sound varies with air density, which is a function of temperature,
pressure, humidity, etc. You can compensate that the same way you do with
a hot wire sensor, ie compare it to a signal propagated through still air.

Christopher OM,

You are right. Let's all remember that the root of the word 'amateur' is the Latin word amo, amare, which means to love. True amateurs do what they do for the love of it; nothing else is required as justification.
I still love ham radio after 43 years of continuous activity, and I operate every day. CU on 40CW.

Thanks to everyone who responded to my request for help.

I managed to get a suitable capacitor from Farnell. They do sell single capacitors, but there is a 10UKP minimum order charge. So I had to get them to send me a copy of their enormous free catalogue so that I could pick some more goodies to make up a minimum order. I doubt that with the price of producing the catalogue Farnell made any profit on the deal!

Look in the ARRL handbook. Just about every one has a little section on using a crt as a rf monitor. Look in the section on measurements. Just deal with the vertical plates on your crt, and leave everything else as is (sweep circuits, etc.). Depending on your output power, you might need to use a small capacitor to sample only a portion of your signal if it doesnt fit on the screen.

I'm interested in hearing from people who are building or seriously considering construction of the transceiver in: "Build Your Own Intelligent Amateur Radio Transceiver."

If you are reading this and unfamiliar with the book, the main project involves homebrewing a 9-band (160m-10m), synthesized, microprocessor controlled rig. Other features include: CW-USB-LSB operation, selectable IF filters, speech processor, adjustable from milliwatts to 50-watts out. The book and additional information is available at a number of sites by searching for the title. 73

I have been watching this thread to maybe learn something. The summary that Tom gave is quite informative. I am wondering where the little monolithic caps fit in. I have some that are square and some that have rounded corners (almost the shape of a silver mica, but tiny caps). Are these of the same ilk as regular ceramic capacitors?

John is right on this point. You need to solder your eyelets after inserting them. I use eyelets for my breadboards all the time but I solder them to avoid intermittent connections. It may take longer but it will save you a lot of heartache later.
